VESICAL OUTLET OBSTRUCTION

By CLYDE W. COLLINGS, M.D., F.A.C.S., NEW YORK, N. Y.

ELLEVUE HOSPITAL, in New York, is a large city hospital containing no provisions for private patients and providing general, no private nursing. Dr. Keyes collected the statistics of prostatic mortality at this pital from 1916 to 1924. He found that of patients entering the urological service suffer- from benign enlargement of the prostate, per cent died in the hospital or shortly after harge.

During this period, gas oxygen was the anesic of choice (except for cystotomy which usually done under local anesthesia).

ince 1924 our practice has changed in several iculars, viz: 1. Spinal is now the anesthetic choice for cystotomy as well as for prostaomy—and we attribute no death to this anesic.

. Preliminary vasectomy has become a routine cedure—in spite of the fact that three patients eloped epididymitis following prostatectomy

. One stage suprapubic prostatectomy has ived more and more preference over the twoe operation—the mortality is less, the wound plications are less frequent and less severe, sistent fistulas are fewer.

here were 187 operations; one cystoscopy was owed by death; 6 died following vasectomy; died after cystotomy; 1 died after cystotomy s a Young punch; 10 died after a two-stage statectomy; 7 died after a one-stage prostaomy; 2 died after perineal prostatectomy; died after perineal drainage of an abscess of prostate superimposed upon an enlarged state.

One hundred and five patients had a supraic cystotomy preliminary to a prostatectomy; per cent died following the cystotomy; 8 reed or were refused prostatectomy; 67 reached statectomy; and 57 candidates survived.

Of the one-stage suprapubic prostatectomy 51 of 58 survived. Of the perineal, 7 out of urvived.

From the Department of Urology, Bellevue Hospital.

We wish to present at this time our surgical results in relieving vesical outlet obstruction in the urologic service of Bellevue Hospital during the past five years. We will consider the following types of obstruction—benign hypertrophy of the prostate gland, carcinoma of the prostate, fibrous contractures of the bladder neck, obstructing scar following prostatectomy, calculus in the prostatic urethra and tumor of the bladder neck.

Symptoms: Over half of the benign enlargement patients (60 per cent) were admitted with acute complete retention; seven others had overflow from retention; the others had the usual symptoms of prostatism—frequency, burning, dysuria, pain in bladder region, and urgency.

On physical examination one patient in four had the bladder distended to or above the umbilicus. After rectal examination, the prostate was described as being *slightly* enlarged, regular and elastic 17 times, *moderately* enlarged 101, and *markedly* 39 times.

Diagnosis: We do not routinely cystoscope every patient with benign enlargement. This examination, at the wrong time, may be just enough to push the patient over the Great Divide. The cystoscopic appearance of lateral and median lobe intrusion need not be described here.

A spinal tap is *always* done when any change in the reflexes is found. I operated upon a tabetic for prostatism this past year. Needless to say the patient was not benefited. All patients have a roentgenogram taken before operation.

We rarely see a normal phthalein test on admission to the hospital. We regard a red test of 35 per cent as excellent for the first two hours after intramuscular injection. Our average test shows 15 per cent. A number of the patients excreted less than 10 per cent in two hours. Such extreme diminution of function has not dissuaded us from operating.

Likewise, there is almost always a retention of the blood constituents, the non-protein nitrogen between 31 and 100 mgms. per 100 c.c., and creatinin 2.0 to 4.5.

One week after operation the nitrogenous products in the blood usually diminish to slightly above normal—in the very sick mounting until just before death the N.P.N. 180 to 300 and creatinin 2.4 to 6.6.

Types of Operation: Of the 187 patients operated upon, 31 per cent had a one-stage prostatectomy, 36 per cent a two-stage prostatectomy, 19 per cent a suprapubic drainage only, 8 per cent a bilateral vasectomy only, 5 per cent a perineal prostatectomy, and 1.5 per cent required a secondary operation for closure of a persistent suprapubic fistula. Seventy-seven patients had a preliminary bilateral vasectomy. In spite of our care in excising a section of the vas, two to three cm. long with all of the surrounding lymphatics and blood supply, three patients developed epididymitis after prostatectomy. However, the swelling and tenderness of the epididymis was slight, lasting for only two or three days. Four patients had vesical calculi complicating the enlarged prostate. These patients were operated upon in two stages because of the more severe infection accompanying calculi.

Up to 1926 it was our custom to tie an indwelling catheter in a prostatic, as soon as he came in the ward. If he tolerated the catheter, we would do a preliminary drainage during the next few days. If the patient was intolerant an emergency suprapubic cystotomy would be performed at once. In ten days to three months, depending upon the patient's condition, the second stage would be done. We consider the functional tests of importance. Equally important is the patient's ability to walk up and down the ward without tiring. This is a true index of the cardiac reserve strength, which is so essential.

A disconcerting complication of the two-stage operation has caused us to abandon it where possible. The suprapubic wound being open for a long time, gives rise to more persistent suprapubic fistulas.

During the past three years we have been doing a bilateral vasectomy as soon as the patient is admitted. An indwelling catheter tied in for from one to three weeks. A one-stage prostatectomy is performed, a Pilcher bag being used for hemostasis. The bag is removed the next morning and a retention catheter put in the urethra at once. With continuous suction on the catheter, the fresh wound heals very quickly; very little infection results, and it is rare indeed we have to operate upon a persistent fistula.

As stated, we have also replaced general anesthesia by spinal (using 100 mgms. of Novocain crystals) during this latter period. We find spinal highly satisfactory and preferable to gas-oxygen. We have not had a prostatic die from spinal anesthesia. However, it is all important that the proper technique be used. We keep the patient on the side, and the head lower than the body. We use ephedrin exclusively to comb the fall in blood pressure.

Of the 135 prostatectomy patients, 9 (6 per cent) had a severe secondary hemorrhage fo lowing operation. Five died two to six days aft the hemorrhage. Six were given a blood tran fusion, 1 died in 20 minutes, apparently fro anaphylaxis.

Record of Deaths: One hundred eighty-eig patients were operated upon, or cystoscoped f an enlarged prostate. One hundred and twen were discharged from the hospital as relieve There were 58 deaths, 1 patient died after cystoscopic examination only, 30 died follo ing a suprapubic drainage, 10 after a two-sta prostatectomy, 7 after a one-stage prostatecto 6 after vasectomy only, 2 after perineal prost tectomy, 1 after drainage of a prostatic absc superimposed upon an enlarged prostate, 1 aft suprapubic cystotomy and a Young punch.

Four patients refused to have the second sta and 6 patients were transferred to another ho pital because it was thought they would n survive the second operation.

The fact that 30 patients died after the cy totomy and only 10 after the second stage illu trates the *relative safety* of prostatectomy up a patient properly prepared as compared to th more or less emergency character of cystoton

Cause of Death: The usual cause of death w renal insufficiency, so-called uremia (22 of patients); 16 died of acute cardiac failu (myocarditis); 6 of pneumonia; 2 of hem rhage and shock; 1 of hemorrhage and urem 4 of septicemia; 1 of pulmonary embolism; 1 h hemorrhage from the rectum and stomach; n from anaphylaxis after transfusion; 1 of php bitis; 1 of pelvic cellulitis; 1 of diabetes and sch ticemia, and 1 of hemorrhage following vas tomy and drainage of an abscess of the gro

Twenty-one patients were operated upon carcinoma of the prostate. More than half patients entering the hospital with this diagnos complained of frequency, inability to urinate, pa in the lower back, perineum or urethra. A f complained of difficulty, hematuria or urgenc

Seven times the prostate was described normal in size, irregular and stony hard; elev times as twice normal size, and three times thrice normal.

The blood constituents in the 19 recorded ca showed an average retention of 47 mgms. N.P.N. and 2.4 of creatinin before operati The N.P.N. averaged 58, and the creatinin after operation. The phthalein ran a para course.

We have used many types of operation up the obstructing carcinomatous prostate. But various treatments proved quite ineffective.

Two patients had a suprapubic cystotomy on

a perineal implantation of radium and deep -ray therapy; 3 had radium by the perineum, suprapubic cystotomy and a Young punch; a transurethral electric excision of the carnomatous bar plus radium through the perum; 2, suprapubic prostatectomy plus radium; perineal prostatectomy; 1, suprapubic prostatomy; 1, had two suprapubic cystotomies for sical calculi due to the recurring carcinomatous ır. This patient also had two radium implantions and finally died of renal insufficiency after ing under our observation for two years. nother interesting case had two kidney operaons for hydroureter and hydronephrosis caused an unsuspected infiltrating carcinoma of the ostate. The autopsy showed the lower end of oth ureters almost completely blocked off.

Deaths: Seven of these 21 patients died; 5 uremia; 1 of uremia and wide-spread metaasis, and 1 of sepsis. Another patient with etastasis to the pelvic bones, was transferred another hospital and would probably have died our ward in a few months.

Where it is possible we like to relieve the tention as a result of carcinomatous infiltration the bladder neck by some type of transureral operation. Any kind of surgical treatment at will keep a patient away from a suprapubic ening is to be greatly desired. Once a suprabic tube is anchored in place, the patient conlers himself an invalid and is a care to everyone comes in contact with.

Several of the members of the staff are using e cutting current through the urethroscope. We ve been able to reduce the residual urine to l or two or three ounces in six instances; the tient previously being in complete retention or ving a residuum of ten to fourteen ounces. a few months or a year, the carcinomatous sue will probably fill in the furrow and the ocedure must be repeated.

The prostate was diminished in size after dium implantation in four of the fourteen cases which it was tried. My personal view of dium in this connection is,—I use it to ease y conscience—it may do some good in a palative way.

Obstructing Fibrous Bar and Scar at Bladder eck: Fifty-eight patients were operated upon this group. As would be expected 43 per cent ere in the sixth decade; 30 per cent in the th, and the other patients about equally divided tween the third, fourth and seventh. One of e patients was fourteen years of age.

The chief complaints were, frequency 36 times, fficulty 19, painful urination 17, complete retenon 13, urgency 12, overflow 5, and hematuria 4.

After rectal examination the prostate was deribed as small, irregular and firm throughout in) per cent of these patients; slightly enlarged in 45 per cent, and moderately enlarged in 5 per cent.

Cystoscopic examination showed a median bar and bas fond in 23 patients, a contracture of the entire bladder neck in 7 patients, slight intrusion of the lateral lobes plus a bar in 6, diverticulum and a bar in 6, and bar plus vesical calculi in 2.

The residual urine before operation varied from 15 c.c. to 600 c.c., average 240 c.c. There were 14 patients in complete retention and 3 with overflow.

Types of Operation: Twelve patients had a Young punch. Eighteen patients had a Young punch under vision through a suprapubic cystotomy wound; 12 had an electric excision of the bar through the urethroscope; 2 electric excision through the suprapubic wound; 6 suprapubic excision with a cold knife; 2 had suprapubic drainage only; 2 resection of diverticulum plus Young punch; 1 had a Fuller punch through a suprapubic wound; 1 perineal prostatectomy plus a Young punch, and 1 perineal prostatectomy. This last patient had a persistent perineal fistula. Obstructing scar tissue at the vesical outlet was electrically excised and the fistula closed. Two of the Young punch patients were operated upon a second time.

Results of Operation: Thirty-three patients had some type of Young punch operation. Of these, 8 died—a mortality of 24 per cent. The cause of death—2 sepsis, 3 of uremia, 2 of hemorrhage and uremia, and 1 with acute abdominal distention. Sixteen of this group were discharged as "improved"; 4 had persistent fistulas (1 closed later following electric urethral excision), 1 discharged with an indwelling catheter, and 5 were discharged with a residual urine of one, two, four, eight, and nine ounces, respectively. Among the twelve electric excision of bar patients there were no deaths; 10 were discharged as free from residuum after operation; 1 with three ounces, and 1 with a persistent suprapubic fistula when transferred to another hospital. Two patients were relieved of their tight bladder neck by electric excision through a cystotomy wound (urethral instruments would not pass).

Four patients had a suprapubic excision of the bar with knife or scissors, 2 of them had a suprapubic fistula on discharge, the other 2 were discharged as improved in 25 and 41 days. Two patients had a suprapubic drainage only—1 died and the other was transferred to another hospital on account of a cardiac condition. One patient was relieved by a Fuller punch through an open operation.

A summary of two of obstructing scar cases following prostatectomy are of interest—Case 1; aged 78, was admitted to the hospital in August, 1926, with a suprapubic fistula following a prostatectomy performed elsewhere. Cystoscopy

tal phenomena in terms of diseased structure, especially of the brain. Thus the organic point of view came to dominate the field and the diagnosis of hysteria was frowned upon, so that the treatment of these cases was left to cultists, quacks and ministers.

The first modern conception of the neuroses was introduced by Charcot, who discovered that hysterical manifestations could be produced by a "pathogenic idea." Further studies by Bernheim showed the tendency of the human mind to accept without proof, and, even contrary to reason, assertions made by others, provided the recipient was in a suitable mood. This native capacity for suggestion was the cause of hysteria. Pavlov formulated a biologic approach to the mental phenomena, while Freud's idea was purely a psychologic concept of the etiology, development, and treatment of the neuroses. According to Wechsler, it is quite probable that some day the neuroses will be explained in terms of neurophysiology, or by further studies in biophysics, or perhaps more knowledge of the endocrine glands.

There is no uniformity in the theories concerning the etiology of the neuroses, although practically all writers agree there is some sort of constitutional predisposition and perhaps some hereditary factors. The *biological* theory holds that neuroses are instinctive reactions of an individual in relation to the social group as a means of protection. These are primary instincts, regarded as inherited reflexes, in which every individual will react in a definite manner to given situations without having had previous experience. There is also a constant reaction for self-preservation and in times of great stress, as seen in wars, neurotic symptoms become an unconscious defense reaction in which imaginary sickness represents a great gain and thus spares the neurotic from the danger of destruction or the accusation of cowardice. Similarly. the struggle for everyday existence with its economic battles exposes the predisposed individual who cannot face reality and who seeks protection, perhaps involuntarily, by means of the neuroses.

The *organic* theory represents a physical or biochemical change in the cerebrospinal and vegetative systems induced by endogenous or exogenous toxins produced by exhaustion, infection, or local trauma. However, only a small percentage of persons exposed to these conditions develop neuroses so that they can only be regarded as exciting or precipitating causes superimposed upon a suitable or impressionable subject.

The *physiologic* theory suggests a "functional" disturbance of the brain, such as a breach at the synaptic junctions with consequent dissociation at different levels of the neuraxis. Paralyses and anesthesias are the result of the interruption at those levels which prevents the passage of centrifugal or centripetal stimuli. There may be a raising or lowering of the threshold in nervous stimuli due to various factors.

The *behavioristic* theory implies that all behavior is but a series of physiologic responses or conditioned reflexes. Experience and training alone account for the reactions. If one can direct the formation of those reflexes, that is, establish the conditions, one can create physioligic pathways and make and also unmake neuroses. Danger and fright can call forth instinctive reactions and establish behavior patterns. The most common view in this theory is that neuroses are caused by or are the result either of auto- or hetero- suggestion.

The *glandular* theory bases the production of neuroses on the dysfunction of the endocrine glands. For example, the gonads, influencing sexual function, play an important part in the production of neuroses. There are also other evidences that the endocrines play a part as seen in the "lump in the throat," tremors, salivation, sweating, and diarrhea in the early cases of hyperthyroidism. Then there are headaches, nausea, and apathy in cases of hypo-adremia.

A classification of the neuroses is as diverse as the theories of their production. However, Dercum separates them into four groups:

(1) Psychasthenia (2) Hypochondria (3) Neurasthenia and (4) Hysteria.

(1) Psychasthenia is defined as a condition where there is a preexisting neuropathy plus nervous exhaustion, so will not be considered in this paper.

(2) Hypochondria is the suffering from a fixed conviction of illness without existence of functional or organic disturbances. The patient fixes his attention to some "internal" ailments and constantly gives some somatic expression to them without any real pain sensation. His bowels do not work, his stomach does not digest properly, his gonads do not function. The essential thing is that the hypochondriac is forever busy with his bodily functions, doing something to make his organs work, always seeking medical or quack relief and never getting it.

(3) Neurasthenia is a fatigue neurosis. The cardinal symptom is ready exhaustion, either mental or physical. Perhaps due to modern civilization with its undue expenditures of energy there results an over fatigue which if long continued results in a condition in which the normal amount of rest and food no longer suffices to restore the organism to the normal equilibrium. A symptom complex established is undue irritability, ready exhaustion and exaggerated response to outside stimuli. The symptoms may also be divided into (1) *Motor,* as ready fatigue irritability, increased reflexes; (2) *sensory,* as fatigue sensations, aches and pains, ready exhaustion; (3) *psychic,* as incapacity for sustained mental effort, diminution in concentration, lessening in spontaneity of thought,

and diminished self-control; (4) *somatic,* in which symptoms everywhere indicate deficient innervation and deficient inhibition. This last group concerns us most in considering the visceral neuroses. As functions of every organ of the body are governed by centres in both the spinal and cortical level to and from which impulses are transmitted to these centres, it naturally follows that such disturbances of the nervous system as are found in neuroses should give rise to disturbances in these functions. The centres which have been localized in the cortex are the motor, sensory, vasomotor, trophic for skin bones and points, cardiac, respiratory, laryngeal, gastric, mascitory, intestinal pancreatic, hepatic, salivary, renal, vesicle, genital, lachrymal, speech, visual, auditory, smell, taste, psychic, and possibly for temperature and metabolism. The centres whose disturbances are concerned in this paper are those which preside over the functions of the internal organs and the vasomotor, which regulates the circulation in them. Impulses pass to and from these centres by two paths. Those for *function* pass through both the pneumogastric and spinal centres and thence by the former nerve or spinal nerves through their sympathetic branches to the organs. Those for *impulses* from the cortical vasomotor centres pass downward to the centres in the spinal level and thence by the branches of the spinal nerves to the organs. These latter branches of the spinal nerves form what was previously known as the sympathetic system.

It is not surprising, then, that any mental disturbance which disorders the control of the psychic centres over those centres which control the functions of the internal organs, should result in disturbances of their functions. Striking examples are vomiting or indigestion from fear or disgust, urinary disturbances due to emotion, rapid heart action in excitement, contracted pupils in anger, etc. In this connection it is interesting to note how the mind can influence the course of *organic* disease by the production of depressing emotions, which lower resistance and hasten the invasion of bacteria, or of the pleasing emotions such as belief in cure, which tend to hasten recovery. The physical effect of disturbances of psychic control over the cortical centres of various organs of the body shows itself by disturbances of their function and changes in their circulation. A few instances are the paralyses, muscular tremors and spasms, anesthesias, parasthesias, hyperesthesias, phyeresthesias, local anemias and hyperemias, edemas and perspiration. In neurasthenia, the irritable weakness of these centres manifests itself in a feebleness of function and unnatural reaction from slight causes. Examples are the habitual cold, clammy skin, easily induced flushing and perspiration, unsteady pupils, easily exhausted reflexes, and easily induced muscular fatigue.

Circulatory neurasthenia is characterized by rapid feeble heart action, pulse 100-160, orthostatic tachycardia, palpitation so violent as often to cause oppression, pain, suppressed voice, pallor, and syncope, cyanosis, and absence of radial pulse. There may be functional murmurs, urticaria and dermographia.

The *gastro-intestinal tract* in neurasthenia may show a loss of digestive power, pain following meals, gaseous fermentation, gastric distension, often vomiting, due to altered secretion and muscular relaxation. Enteroptosis and constipation are common findings, and the patient complains of anorexia and eats just from sense of duty. He may associate certain foods with gastric disturbances and often eliminates them from his diet, and because he is afraid of a recurrence of these disturbances these articles are permanently dropped, so, that often his food is reduced to just milk or soup. Anemia, acidosis, and emaciation frequently are seen following such a dietary restriction by the patient.

The *respiratory system* presents feelings of choking, stitch in side, or pains in the chest. There may be an increased rate of respiration but no true dyspnea.

In neurasthenia the *genito-urinary system* is often affected. There may be large amounts of urine of low specific gravity or small amounts with high concentration. The laboratory findings may show traces of albumen, occasionally slight glycosuria, but no casts. In the male there may be faulty erection, premature ejaculation, diminution of the sexual appetite. In the female —irregular menstruation, pains in the back, and tenderness in the ovaries are common findings.

The *eyes* may be affected as loss of power of the muscles of accommodation resulting in blurring of vision, fatigue of the retina causing narrowing of visual field, photophobia, pain in the eyes. The *auditory mechanism* may be impaired by subjective sensations of noise.

The other main group to be considered is (4) Hysteria, and it should be regarded as a real clinical disease because of the general uniformity and character of its symptoms. It is defined as a disease of suggestion, but it is often found in persons who are ignorant of such a thing as hysteria and who frequently will simulate a disease which they have never seen or heard of. The condition is usually the result of some profound mental shock or emotion and is most often seen in persons with impressionable nervous systems. There is hardly a sign or symptom of organic disease that hysteria cannot simulate. The hysteric subject may present moods, anxiety, character or personality disturbances, and somatic manifestations. Of these latter conditions hysteric *pain* is the most common, and it may be "neuralgic," "migrainous" or "rheumatic" and may occur anywhere in the head, body or limbs.

The pains may be diffuse as to include a large area of body surface or an arm or a leg. Or it may be localized to a small area of the scalp, the tip of the coccyx, or the little toe. Pains in the abdomen may present the picture of a peptic ulcer, an appendix, gall bladder disease, or renal calculus. Pains in the limbs are often accompanied by anesthesias, paresthesias, etc.

Hysterical paralyses, partial or complete, flaccid or with contractures, may occur. Usually there is no atrophy at first, no loss of reflexes, no reaction of degeneration. The gait may simulate most any ataxia. Often a patient will be unable to walk but may swim, crawl, or even run. Aphonia is the most common form of psychogenic paralysis and may be sudden in onset, following great emotional stress.

In the *gastro-intestinal tract* hysteria may produce anesthesia of mouth, lips, tongue and pharynx, with absence of gag reflex. Hysteric coughing, yawning, belching and hiccoughing are common—the latter being caused by spasms of the diaphragm, and is usually crowing in character.

Globus hystericus, esophagospasm, dysphagia, and pylorospasm are common manifestations. Some cases pretend to refuse all food for the purpose of exciting interest and when accompanied by persistent vomiting may result in extreme emaciation and inanition. Vomiting may represent a pregnancy phantasy or may be the result of some disgusting dominating obsession. On the other hand, some of the "pernicious" vomiting cases seen in true pregnancies are hysteric in origin. Hysterical edema of the stomach, with or without transudation of blood, may cause indigestion, vomiting, epigastric pain, tympanites and abdominal pulsation. Abdominal distension at the time of the menopause may simulate a pregnancy (pseudocyesis), especially when accompanied by amenorrhea, usually common at this time. Aerophagy, or swallowing of air is common, as are borborygmi, or abdominal noises, and often startling expulsions of flatus. Hysteric constipation is very common, which leads to the self-gratifying habit of daily enemas for the neurotic. Diarrhea may be the result of a nervous mucous colitis due to disturbance of both the secretory and motor functions of the intestine and are frequently diagnosed as enteritis.

Paroxysms of rapid shallow respiration unaccompanied by dyspnea, may be seen. Other *respiratory affections* are occasional paralysis of the vocal cords and edema of the glottis.

Paroxysmal tachycardia with precordial distress may result in a picture of pseudo-angina pectoris. Vasomotor disturbances may produce blanching or blushing of the skin, cyanosis or edema, dermographia, rectal or vaginal pruitis.

The *renal system* presents a wide variation of conditions. There may be polyuria, due to dilatation of the renal vessels causing a secretion of a larger amount of urine of low specific gravity. A renal edema may be present with this dilatation resulting in small amounts of albumen appearing in the urine. The opposite condition of anuria may result from the contraction of renal vessels causing a diminution or temporary suppression of urine. Incontinence may result from hyperesthesia of mucous membrane of the urinary tract, or there may be retention due to anesthesia. The genital system may show excessive, prolonged, or too frequent menstruation due to vascular dilation, or scanty or suppressed flow because of vascular spasm. Hyperesthesia or anesthesia of the mucous membrane of the vagina frequently is the cause of marital incompatibility.

Hysterical fever resists all antipyretics and, being continuous, or irregular, often simulates typhoid, tuberculosis or meningitis.

Muscular spasm, strabismus, hysterical corneal anesthesia may affect any organs of sight. There may be hyperthesia of hearing and occasionally loss of auditory memory.

The diagnosis of the neuroses is most important because herein rests the prognosis and treatment of the patient. Four points must be borne in mind: first, the differentiation of psychogenic from organic diseases; second, the differentiation of one neurosis from another; third, the differentiation of the neuroses from the psychoses; and fourth, of the neuroses from malingering. The profession, in general, regards the diagnosis of neurosis as a dangerous one, and it should not be made on exclusion alone. It should be made with caution on a patient over forty whose nervous mechanism has previously been sound, because the history of a neurotic is usually traceable to infancy, adolescence, or perhaps an inherited instability. Also a patient with definite organic disease may have neurotic symptoms engrafted upon it. The absence of Babinski's sign, unequal reflexes and the like does not necessarily speak for a neurosis, and again, incipient organic conditions as latent carcinoma of the spine, postencephalitic tic or spasm, or early cerebral arteriosclerosis may lead to the erroneous diagnosis of neurosis because of the temporary absence of physical signs.

In practice, clinics and hospitals, one seldom meets with hysteric paralyses, blindness, anesthesias, gait anomalies, etc., but most commonly one sees the anxiety neuroses, phobias, and neurasthenia. The age is most common within the years of greatest stress, as between thirty and fifty. As Bassler says, "Cases of true neurosis are seen in individuals old enough to care for themselves and others, and young enough to engage in the many activities of life. While not exempt in the child, or the aged, the nervous

organism is less impressionable to the establishment of neuroses in the first, while the waning digestive power, less activity of life, or discretion from years of experience seem to form a sort of immunity in the second." As to social status, no group is exempt, but neurotics are more frequent among brain than hand workers. Exciting causes may be stated as overwork, emotional stress, trauma, infective fevers, chronic intoxications such as lead or arsenic, and exhausting conditions as seen in cases of hemorrhage or starvation.

Hyperthyroidism may have only symptoms of anxiety in its early stages and a careful search must be made for an enlarged thyroid gland, ocular signs, and increased basal metabolic rate.

Multiple sclerosis must be carefully considered, but the presence of true nystagmus, absent abdominal reflexes, pallor of the optic discs should exclude hysteria.

Epilepsy usually can be ruled out because in hysteria there is no true unconsciousness, tongue biting, absent pupillary reflexes, incontinence, or history of injury during falls in attacks

Brain tumor must be borne in mind in cases of prolonged headache, but careful observation over an appreciable length of time should establish the diagnosis.

Caries of the spine is occasionally mistaken for hysteria so that careful *x*-ray studies should be made.

Encephalitis lethargica often stimulates hysteria in its incipient stage.

Pernicious anemia must be ruled out in cases of pains in limbs accompanied by paresthesias, hyperesthesias. Often hysteria will have these dysthesias together with dysthesia of the tongue and mucous membrane of the mouth so that a picture of pernicious anemia may be presented.

Gastro-intestinal neuroses often present difficulties in diagnosis. Pain, anorexia, gaseous eructations may simulate organic disease, but usually the vomiting is not related to meals, is unaccompanied by definite pains, and *x*-rays of the gastro-intestinal tract should rule out ulcers or neoplasms. A good point to bear in mind, since neuroses are conditions of middle life, is that in the two extremes of ages, digestive disturbances are more commonly due to dietetic errors in the young, or in the old to neoplasms or waning digestive power.

The *renal system* with urinary symptoms often presents a picture of nephritis, but lack of casts and practically normal kidney function tests rule it out.

Respiratory system hysteria may present a classical case of pulmonary tuberculosis with cough, anorexia, loss of weight, nocturnal sweating, and even pulmonary hemorrhage. Here again a correct diagnosis should be established with the help of the laboratory and *x*-ray.

Briefly in differentiating neuroses from psychoses one must note the following points: The neurotic seeks adjustment, while the psychotic is anti-social. In neuroses the symptoms are *real* to the patient, while the malingerer *purposely simulates* a disease for some gain. The malingerer usually resents frequent physical examinations, while the neurotic welcomes them.

Treatment must depend upon the individual case and conditions appertaining to it. The patient must be taken seriously and should never be told that his ills are imaginary. A patient with neurotic headaches or indigestion is really ill and it is useless to tell him to "forget it," that there is nothing wrong with him. In fact it only tends to make him worse because he is sure that he has some rare disease that defies present day diagnosis or treatment. If no organic condition is found, the patient should be assured of the fact, but also be told that this does not mean he is not sick. It is best to explain to him how shock, sex, social conflicts, worry and present day mode of living may be capable of causing nervousness, and that mental upsets may be responsible for all kinds of physical ailments. Then one can explain plausibly to him that if these mental upsets can be remedied, the physical conditions will then be cured. However, care must be taken not to preach to the patient or assume the role of a moralist.

Foci of infection should be carefully removed. Rest with an occasional change of surroundings, or "milk cures," especially in emaciated subjects, may be beneficial. Suggestion has met with some success, particularly in cases of anxiety and phobias. The use of the endocrines is in its infancy. Electr d massage are often be exercised in the us hypnotics for insomnia, laxatives for constipation, and enemas play into the patient's hands. In general the less medication the better, and usually a bitter tonic or some other placebo is best. Always bear in mind that a patient who has the native capacity for suggestion and the development of a neurosis, has that same receptive mood for accepting suggestions that may effect a cure.

MEDICAL AND SURGICAL ASPECTS OF ACUTE BACTERIAL INFECTIONS

PAPERS PRESENTED DURING THE THIRD GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE, ABSTRACTED BY FREDERICK P. REYNOLDS, M.D., MEDICAL SECRETARY, COMMITTEE ON MEDICAL EDUCATION

Third and Final Article. No. 1 is in the Journal of December 1, pages 1397-1403, and No. 2 in the Journal of December 15, pages 1471-1478

DR. FRANK L. MELENEY

Surgery, application of heat, blood transfusions, and continued research in the use of the ultra-violet ray were advocated as promising methods of dealing with skin infections by *Dr. Frank L. Meleney,* Assistant Professor of Surgery at Columbia University, in a paper entitled "Infections of the Skin and Subcutaneous Tissue —Including Infections of the Fingers and Hand."

"In recent years," he said, "ultra-violet light has been given a great deal of credit for improving the general body resistance. We do not know how it acts; the subject is a relatively new one but it offers an encouraging field of research which in the future will almost certainly rationalize this method of treatment. Still more recently the question of vitamin deficiency, as a predisposing factor to infections, has been given a considerable amount of attention both by clinical and laboratory observers. Vitamin B, has been considered the most important vitamin element, the ingestion of which increases the body's resistance to infections. Here again the question has not been settled, but the popular use and abuse of yeast is one of the results of this investigation. It has been said that the normal diet of man has an excess of this vitamin, but where the patient can not take the normal diet, it is possible to increase to a considerable extent the intake of vitamin B.

"Transfusions are being used more and more in the treatment of infections, but there is no unanimity of opinion with regard to their real virtue inasmuch as protective antibodies are not present in serum and the relatively small number of leucocytes transferred could not be expected to have any particularly favorable action. In anemic cases resulting from the prolonged infection of hemolytic organisms, transfusion is of real value but I have seen transfusions used repeatedly in the acute stages of infection without any definite improvement in the condition of the patient and certainly transfusion should never be made a substitute for the proper surgical procedure. On the other hand during convalescence, after the acute process is under control, transfusions do a striking amount of good, perhaps boosting the patient more than any other form of treatment. The use of medicines in these infections is of very little avail.

"In our treatment of well established infections, our resources are limited. We are reduced to two main methods of treatment,—namely, surgery and the application of heat both used with painstaking care and the soundest surgical judgment available.

"A clear knowledge of the anatomy of the skin as well as the tissues just beneath the skin is necessary for the understanding of the development and progress of these acute infections, for the anatomy as well as the physiology of the skin, affects in no small measure the course of events.

"After the initial signs of inflammation appear, the course of events depends upon the balance of the forces pitted against one another and the structure of the battleground over which they struggle. The battle may exhibit any degree of intensity.

"While we have been considering how the bacteria spread from the site of the original focus, what has the infected host been doing to combat this spread? The less resistant bacteria are destroyed and the less resistant cells are destroyed. Here we have a survival of the fittest so that as the bacteria which survive proliferate, the more resistant qualities are propagated from generation to generation.

"It is of importance for the surgeon to know the organism causing the infection. At times the site of the lesion and the nature of the injury will enable one to predict, with some degree of certainty, the species of organism which has been introduced and the type of infection which may develop. For example, the infections which arise following a human bite are known to carry a mixture of mouth organisms which produce a fairly characteristic initiation and course of infection. Lacerated wounds, produced by fragments of shell in war time, carrying in clothing and soil, are known to frequently result in an infection with the organisms of the soil and feces, gas-gangrene, tetanus and the like. Infections which develop after operation, particularly where the tissues have been uncontaminated before, are known to yield the organisms which are common in the air or in the nose and throat of the operating personnel.

"In general it may be said that when a wound is infected with two or more different varieties of organisms the infection is more severe than if only one of these types is represented.

"With the foregoing general principles in mind, how shall we treat infections of the skin and subcutaneous tissues? The purpose of the surgeon in his treatment of all of these conditions should be to restore the part to its normal form and function as soon as may be. The ideal result

would be a resolution of the part without any evidence of destruction of tissue but more often than not when an infection is well under way, the surgeon's knife may be called upon to destroy superficial tissues in order that there may be a cessation of further destruction of the deeper structures.

"Prophylactic measures with regard to those infections which appear to be more or less spontaneous but which arise from organisms entering through hair follicles and sebaceous and sweat glands, consist in frequent washing of the skin with hot water and soap particularly after the exposure of the body to known sources of contamination. This especially applies to doctors and nurses who frequently handle infected wounds. The prophylactic treatment of infections which arise in wounds has of course been given great consideration by countless doctors in times past. This is more important and more difficult than that which we apply to avoid spontaneous infections because of the variability of the depth and extent of the wound and the variety and number of the organisms and other foreign bodies which are introduced into the wound. Our whole surgical aseptic technique is prophylactic against these infections in operative wounds. When wounds have occurred from injury, we must assume that organisms have been introduced and from our experience we may estimate to some degree the number and kind if we know the conditions under which the injury took place. The chief prophylactic measure is the removal, as completely as possible of these organisms and other foreign bodies from the wound Likewise, any injured tissue which the part can safely spare and which might favor the growth of those bacteria which remain, should be excised. The former can frequently be carried out to a considerable extent by the patient himself or the lay members of the family, if a doctor is not immediately available but the doctor must review this preliminary treatment and carry it further if necessary. Certain life insurance companies have circularized the public with regard to this important step in the prevention of wound infection and have particularly advocated cleansing rather than the use of antiseptics for fear too much reliance should be placed upon the latter and the cleansing be neglected. This emphasis on the cleansing can not be too greatly stressed but with the wound as clean as possible, antiseptics may be used and in my experience, Dakin's solution, bichloride of mercury, mercurochrome or iodine locally do more good than harm, and their efficiency probably rates in the order named.

"Vaccines have been used more extensively than sera in the treatment of these cases and have been given the credit for marvelous cures for which there is little evidence.

DR. HANS ZINSSER

Dr. Hans Zinsser, Professor of Bacteriology and Immunology at Harvard University Medical School, Boston, delivered the Carpenter Lecture of the year. His subject was: "Immunity—General and Local."

Discussing the physiological significance of immunity, natural and acquired, and the relationship between the significant chemical constituents of the bacteria and cells in antibody formation, Dr. Zinsser said that "the principles that govern resistance to bacterial infection in general are applicable to a limited degree only in tuberculosis and syphilis, and are still less so in the protozoan diseases and infections caused by filtrable agents. One of the developments of modern immunology is the recognition of a number of variants of the defensive mechanism about which we cannot generalize from our knowledge of immunity in the bacterial diseases."

Discussing the enhancement of the natural defenses of the body against diseases, Dr. Zinsser said that immunology like other branches of knowledge has had alternating periods of rapid advance and apparent stagnation.

"Immunity in its broad connotation is the study of the reactions of animal and plant tissues to foreign materials which can neither be utilized for nutrition nor excreted without alteration. The various responses which are initiated by the entrance of foreign materials constitute inflammation, and this term—though usually applied to the local reactions—should be physiologically extended to include the deeper consequences which take place in remote regions of the body. Conceived in this way, inflammation is the consideration of natural immunity by which all animals and plans, not previously infected, defensively respond. The forces of natural resistance are normal reactions, and physiological emergency apparatus, called into play when foreign materials enter the tissues. The chief difference between natural immunity and acquired immunity to infectious disease is that which results from the antigenic properties of the bacteria and their poisons. In regard to the mechanism of specific antibody production, we are quite as much in the dark as we have ever been."

Dr. Zinsser said that observations "strengthen a growing impression that we must look upon the skin as a special organ, with individual functions and reaction capacities considerably more

far reaching than its mere significance as integument.

"We must accept as a fact that the injection of many substances—particularly bacterial proteins, foreign sera, etc., may exert a profoundly beneficial, sometimes curative effect upon a variety of acute and chronic infections, provided dosage and activity of the chosen substance are appropriate to the physiological responsiveness of the patient. By this we mean too large a dose may be as harmful as an appropriate dose may be beneficial and that a material and dosage likely to give excellent results in a vigorous patient may perhaps be harmful in a patient already considerably enfeebled. It is, therefore, a therapeutic procedure not without danger, but it cannot be ignored as an important field of study.

"As a natural corollary to studies on methods of reinforcing natural resistance there is developing a growing interest in problems of host susceptibility. There are many infections to which man is so highly and uniformly susceptible that practically all previously uninfected individuals contract them, if thoroughly exposed. Thus there are no significant differences in human susceptibility to measles, mumps, small pox, influenza, cholera, plague and some other diseases, and the supposedly greater susceptibility in childhood can be shown to be fictitious and attributable to the fact that exposure and consequent immunization is sure to have occurred before adolescence.

"There is no other class of disease in which the average resistance of the normal human being is relatively so high and in which infection occurs, as a rule, in the training of predisposing diseases or of fatigue, exposure to sudden changes of surface temperature and other accidentally depressing factors which let down the bars that ordinarily prevent penetration.

"There has been much evidence in the post-war increase of tuberculosis in certain European countries which has suggested direct relationship between the incidence of tuberculosis and fat deficiency. The time honored used of cod liver oil may depend upon its fats—or more probably upon its vitamins—but there seems to be little doubt of its actual beneficial influence. The suggestion of dietetic relationship to susceptibility is not a recent one. That nutritional disorder predisposes to infection seems likely.

"The protective serum body is not an antibody in the usual sense. It persists in the blood of convalescents for years, and it cannot be increased by hyperimmunization to anything like the extent that this can be done with bacterial antibodies."

Dr. Zinsser concluded that of all the biological branches of medicine no other is more deeply involved with the problems of the clinic than immunology.

DR. WILLIAM H. PARK

Reviewing the use of serums in combating contagious diseases like diphtheria, tetanus, scarlet fever, erysipelas, meningitis, poliomyelitis and pneumonia, *Dr William H. Park,* Director of Laboratories of the Department of Health of New York City, reviewed the marked progress in the field and declared that he doubted "whether any case of diphtheria has ever developed within a week after a person has received 1,000 units of antitoxin."

He discussed the therapeutic use of various sermons and methods of administering them. Among other things he said:

"The first disease I shall touch upon is diphtheria. There is probably little new that I can say to you on the use of antitoxin in this disease.

"The use of antitoxin to produce passive immunization against diphtheria is exceedingly successful. I doubt whether any case of diphtheria has ever developed within a week after a person had received a thousand units of antitoxin. We must remember that this passive immunity is not lasting. It is quite different from that which develops after toxin-antitoxin or toxoid. It is interesting to note that in the 35 years which have elapsed since the discovery of antitoxin and the twelve years since the general use of toxin-antitoxin or toxoid, that the death rate has been reduced from 150 to about 5. Undoubtedly, the severity and mortality of diphtheria would have lessened considerably during these 35 years, owing to general health measures, but the most careful scrutiny of the facts makes us confident that much of it is due to diphtheria antitoxin and to toxin-antitoxin.

"The next disease that I wish to discuss is tetanus. Every clinical case of tetanus is a late one. There is in the infected wound no suggestion of tetanus. It is only when the nervous and muscular systems have become involved that we realize that tetanus texin has been acting for some time. There are only two proper methods of administering antitoxin in tetanus. One is through intravenous injections, the other through intraspinal injections. These should be combined. Experimental evidence shows us that an animal can be saved by an intraspinal injection when it cannot be saved by an intravenous injection, and the majority of those who have had most to do with the treatment of tetanus, believe that that the same is true for the treatment of human beings. We have just stated that in diphtheria we only give one dose of antitoxin. In tetanus

we give several doses. We have some evidence that is advisable to keep the antitoxic content of the spinal fluid and of the blood at a high level. It is possible that the first injection of the antitoxin both intraspinally and intravenously accomplishes nearly all the good that successive treatments accomplish. However, the disease is such a dreadful one that we want to do everything that seems to be of possible avail. We must remember that in the severe and rapidly advancing cases, that antitoxin will probably be given too late to do any good. It is the moderate cases which would probably be fatal without treatment that antitoxin shows its best effect.

"Scarlet fever infection is due to strains of hemolytic streptococci. These produce injury through both extracellular and intracellular toxins. Scarlet fever antitoxic serum is obtained from horses injected with a strain of maximum range of toxin production. The horse should respond markedly to all the different toxins. Such a serum has a marked neutralizing effect on the toxin in the patients during the first few days in the great majority of cases of infection.

"In erysipelas the streptococci are more variable than in scarlet fever. We have had very little personal experience with the use of the antitoxin serum, but from the literature and from personal communications, we believe that good results are obtained from its use. The antitoxin must match the toxin. This is secured by injecting the toxin obtained from several types. The dosage is the same as in scarlet fever.

"It is well known that antimeningococcic serum has been used in the treatment of meningococcic meningitis intraspinally for about 23 years. For the past twenty years, its use has been very general. Earlier than this, in 1905-6, a serum was produced at the Research Laboratory which was administered intramuscularly without definite results. The value of the antimeningococcic serum intraspinally is almost universally accepted.

"It has been repeatedly reported to us by physicians in the army overseas, that while poor results were obtained by the use of many sera, uniformly good results were obtained by the use of the serum from the Pasteur Institute in Paris and from the Research Laboratory in New York City.

"During the past twenty years, fashions have changed from time to time in the method of administering the serum. In the earlier days, the serum was given intraspinally once in 24 hours for four doses and for a longer time if the fluid did not become sterile. A rather moderatly sized dose of serum, about 20 cc., was advised at that time. Since then certain workers have advocated a more intensive method of treatment. They have administered the serum intraspinally every twelve, eight, six or even four hours. It has also been recommended that the serum be given intravenously or intramuscularly or both in all cases in addition to the intraspinal administration. This intensive method of treatment was greatly in vogue during and shortly after the war, but a study of the mortality in certain institutions where this method was carried out, has been very unconvincing as to its value. Indeed, the mortality of cases thus treated has been generally much higher than those treated more conservatively.

"The Meningitis Division of the Research Laboratory has quite consistently followed a conservative method of treatment. The physicians of this division as a rule administer 20 cc. of serum intraspinally every 24 hours until at least two spinal fluids are free from organisms both by smear and culture. Additional doses of serum may be given if after the serum has been discontinued for a short time, the patients fail to continue to improve or if spinal fluids withdrawn to relieve pressure, show a return of the organisms. While it is generally accepted that the meningococci invade the blood stream for a short time before localizing in the meninges, it has not been the experience of the Meningitis Division that it is advisable to give serum intravenously except in those cases where there is a prolonged septicemia as shown by repeated positive blood cultures or by a persistence or recurrence of the hemorrhagic rash. Occasionally a case of true meningococcemia is seen without the development of a meningitis. In such cases, serum intravenously is indicated.

"The serum treatment of other purulent forms of meningitis has been discouraging.

"Three different sera have been used in the treatment of poliomyelitis.

"Convalescent serum has been used quite extensively and certain observers claim that it is very valuable if administered in the preparalytic stage."

DR. ERNEST E. IRONS

Dr. Ernest E. Irons, Clinical Professor of Medicine at the Rush Medical College at the University of Chicago, in an address on "Facts and Fancies Concerning Vaccines and Non-Specific Therapy" said that "the present wave of popularity of injection of foreign proteins for diseases of all descriptions is likely soon to pass as have all modes and styles.

"In matters of dress, which vary from long skirts to short and back again, the original object of clothing to protect the body from cold and injury seems at times to be lost sight of, and in

medicine newly observed or striking effects lead to the revival or popularization of remedies without due regard to ultimate results, on the assumption that these effects are necessarily beneficial to the patient," he continued. "The occurrence of the changes is evident; their value to the patient requires careful consideration. The ease of use of the hypodermic needle which makes possible the parenteral introduction of proteins into the body has led to widespread and often uncritical use of this method in the treatment of all manner of conditions and to the drawing of clinical conclusions often without consideration of the natural history of the diseases treated.

"In the study and attempted therapy of infectious disease of the past 40 years, chief emphasis has been on the specific relationship of cause of the disease and its proposed remedy. The early success of diphtheria antitoxin, and the conceptions of most workers, influenced greatly by the teachings of Ehrlich, tended to direct therapeutic efforts along specific lines, and when treatment by antisera or vaccines was attempted, the causative organism of the disease was used. When specific vaccines failed to yield results expected, it was thought that perhaps by using a vaccine prepared from the identical organism causing the disease in the patient (autogenous) better results might be obtained.

"The verdict of 1,500 jurors selected alphabetically and only on the basis of their willingness to serve, indicated that the great expectations of 1906 to 1912 for the general usefulness of vaccines, had not been fulfilled, as shown by the fact that in all but 5 of 63 different disease conditions for which vaccines had been recommended, the percentage of physicians not using or no longer using them was nearer 100 than 90 per cent.

"The span of the rise and fall of the cycle of vaccine popularity was about 15 years. About the time when vaccine therapy in general had passed the peak of its popularity attention was directed anew to some of the reactions which occur in the animal body following the parenteral introduction of foreign protein whether of bacterial or other origin. While non-specific protein therapy has come into prominence in the past 10 years it has been used in some form or other for many decades.

"Even a brief survey of the literature of non-specific protein therapy will reveal an amazing list of different diseases and conditions in which this method has been used and more or less enthusiastically recommended. Included in the list are acute and chronic arthritis, pneumonia, typhoid fever, sepsis, erysipelas, gonorrheal infections, peptic ulcer, bacillary, dysentery, encephalitis, general paresis, dermatological conditions, diseases of the eye especially iritis, thromboangeitis obliterans, arteriosclerotic gangrene, Raynaud's disease, and nephritis. The length of the list does not make a favorable impression on a follower of Ehrlich and it is reminiscent of the still longer lists of commercial vaccine makers of some years ago and suggests that the clinician is already feeling the lack of laboratory control and guidance which, when available, is so steadying and helpful.

"That the intravenous injection of foreign protein produces profound changes in the body is shown both by laboratory tests and by clinical observation. The question we have to answer is not whether such changes occur, but whether they are of advantage to the patient and if so whether the advantage gained offsets any possible disadvantages. We have also to determine whether such improvement as it noted is actually due to the remedy, or whether in the disease in question, similar improvement may occur spontaneously.

"Acute arthritis, due to acute or chronic localized infections elsewhere in the body, frequently heals spontaneously. The swelling, pain and disability disappear and in a few days the joint may function as well as before. In some cases, treatment with foreign protein is said to hasten the return to normal, but whether so treated or not there may be recurrences of the arthritis in the same or other joints. The clinical question here is whether the benefit of hastened cure, by a few days in some instances, is offset by the failures and possible attendant dangers of the treatment in the others.

"The evaluation of the results in relief of pain, disability and deformity, which usually pass under the clinical term chronic arthritis is still more troublesome. There may be present the element of infection, but often the immediate cause of disability is mechanical as in osteoarthritis, or in the damage to cartilage of atrophic arthritis, or in referred pain from nerve irritation or pressure.

"Early reports of treatment of disease by any new method are likely to be over-enthusiastic because pioneering requires enthusiasm and further, because the investigator often is entering a new field, inspired by a theory and lacks any considerable background of knowledge of the clinical course of the disease when untreated or treated by other methods.

"Even in the more favorable reports of results of treatment of arthritis and iritis there is now and then a note of caution. One of the foremost proponents of protein shock therapy in arthritis finds 'that if no benefit is derived after two or three injections it is not probable that further treatment will be beneficial.' This would indicate either that the method works only part of the time, or that it is useful only in a selected group of cases. If the latter, then the treatment should be limited to this group, if it can be defined, and a like group of controls furnished.

"In the patient with chronic arthritis there are usually more than one and often several factors contributing to his pain, deformity and disability.

The chronic feature of the arthritis may be due to the recurrence of acute exacerbations. Such cases are often associated with chronic local infections, and constitute the group of chronic arthritis which affords examples of relief by the eradication of infection.

"The arthritis may be of the atrophic type with swelling and later loss of cartilage and atrophy of muscles, or of the hypertrophic type with proliferation of joint margins and but little muscular atrophy. While infection is believed by some to be one of the chief factors responsible for the former of these two, in both groups other factors including heredity, poor nutrition, metabolic disturbances, impaired local blood supply, trauma resulting from hard work and from increased weight bearing, to mention but a few, play a large part in the production and progress of joint disease and disability. Pain may result from mechanical causes as in hypertrophic or osteoarthritis and may subside spontaneously.

"The permanent relief of pain and disability in chronic arthritis whose otiology is varied and whose course is characterized by spontaneous remissions and exacerbations at intervals of months, seems unlikely to result from the use of one remedy such as foreign protein injections or vaccines, and when improvement occurs following treatment, it seems necessary to reserve some credit for other possible factors.

"Striking results including numerous instances of clinical improvement have been noted following the use of protein shock therapy. For the most part these have been seen in acute conditions rather than in those of long duration. As a routine and sole method of treatment the case for protein therapy has not been proved. It is necessary here to distinguish from this large group, methods of specific immunization and desensitization employed to relieve the symptoms of sensitiveness to specific known proteins such as those of some pollens and foods. Whenever it is proposed to use protein shock therapy, in a special case, due consideration should be given to possible serious and unexpected outcomes. The present wave of popularity of injections of foreign proteins for diseases of all descriptions is likely soon to pass, as have other modes and styles.

"Even though we as a jury may fail to reach an agreed verdict as to the value of foreign proteins on each count and disease, we shall, I believe, agree that the evaluation of clinical evidence requires caution, and shall continue the care and study of patients with honesty of purpose and with due regard to the natural history and progress of disease."

DR. HOMER F. SWIFT

Dr. Homer F. Swift, member of the Rockefeller Institute for Medical Research, speaking on "Rheumatic Fever" declared that it was one of the most important diseases economically, not only because of its acute manifestations but because of its role in the production of between 30 and 40 per cent of chronic heart disease in the latitude of the North Atlantic states. He stated that the disease was often present between the periods of acute attack and that effective treatment of it must take these periods as well as the acute stages into account.

"A number of factors appear to have causative relationships. Climatic conditions such as exist in temperate zones in winter favor its development, while sunny, dry summers and tropical weather inhibit or prevent its evolution! Among the poorer classes it is from 15 to 20 times more prevalent than in persons better housed and fed. Malnutrition and mild toxic states are frequent precursors of characteristic attacks. Most patients, both children and adults, give a history of repeated non-specific infections of the respiratory tract, tonsils, sinuses, or middle ear, extending over several years, before a typical attack of rheumatic fever is ushered in by a severe focal infection. Hence there seems to be a distinct contagious factor favoring its spread. Because chronicity and relapses are so frequent, and crippling cardiac damage is of such gradual evolution, and finally because laboratory tests often reveal activity in periods between attacks, it seems justifiable to consider the infection to be characterized by long periods of preparation or sensitization of the tissues, the result of repeated mild infection before a more intense focal infection sets off the violent explosion recognized as acute rheumatic fever.

"Similar mild infections, moreover, apparently favor the continuation of true rheumatic activity in viscera already involved. It seems logical, therefore, to regard these preparatory periods and mild chronic infections between acute outbreaks as essential parts of the morbid process. Hence our therapeutic and prophylactic efforts should be directed against these chronic conditions as well as against the more acute manifestations of the disease."

CONGENITAL SYPHILIS, ITS MANIFESTATIONS AND TREATMENT*

By EARL D. OSBORNE, M. D., AND EDWARD D. PUTNAM, M.D., BUFFALO, N. Y.

IN THIS symposium on syphilis, time does not permit a complete and detailed description of all the numerous and varying manifestations of congenital syphilis. We will confine ourselves to a brief and concise description of the principal manifestations, their frequency and importance in the diagnosis, and finally a survey of approximately 300 cases seen and treated at the Children's Hospital of Buffalo, Buffalo City Hospital, and in private practice. Two hundred and sixty-four of these cases were seen at the Children's Hospital of Buffalo.

In general, the rule can be formulated that the nearer the time of conception is to the time of infection, the greater is the danger of infection of the embryo, or fetus. In view of the fact that 90% of infections occur between the 17th and 25th years of life, which corresponds to the period of greatest reproductive activity, it is not surprising that 40 to 50% of all pregnancies in syphilitic mothers result in miscarriage or stillbirth. Generally speaking, 3 to 5 years of adequate treatment is sufficient to prevent further syphilitic pregnancies in a syphilitic mother. In contradistinction to older views, however, we have 3 syphilitic women who have been giving birth to syphilitic infants for from 12 to 15 years. Although time is an attenuating factor, it should not be relied upon to prevent the birth of a syphilitic infant. The method of transmission of syphilis to the fetus has been a bone of contention for a number of years. There are 3 theories: (1) paternal origin, (2) maternal origin, and (3) mixed origin. At the present time it is admitted by most syphilologists that the syphilitic mother is the chief if not the universal source of infection of the child, by way of the placenta. The symptomless condition of many mothers, who give birth to syphilitic children, has been in the past a stumbling block to complete acceptance of the maternal infection of the fetus. With the improvement in serologic technique it has now been effectively demonstrated that syphilis is present in the large portion of apparently healthy mothers of newborn syphilitic children. The animal experiments of Brown and Pearce,[1] and careful serologic study of the mothers of syphilitic children, have shown that pregnancy exerts an inhibiting effect upon an acute syphilitic infection which is sufficient to keep the mother apparently symptom free, even though the child may develop obvious signs of the disease. We are aware that successful inoculations of rabbits with semen from syphilitic patients have been made by Finger and Landsteiner,[2] and by Eberson and Engman,[3] but until a rest form or granular form of the spirocheta pallida is demonstrated, there is no absolute proof of the paternal transmission of the disease.

Fetal Syphilis

Theoretically, the embryo of the fetus may be infected at any time during its development in utero. Infection of the embryo during the first 2 or 3 months results in abortion in the 3rd to the 5th month of pregnancy. Infection of the fetus after the 3rd month leads to fetal congenital syphilis, with all the cutaneous mucous membrane and visceral lesions, with death of the fetus in utero, or a living syphilitic infant. Maceration of the fetus is probably the most diagnostic sign of fetal congenital syphilis. The heart and liver, and other viscera are severely involved. The abdomen is protuberant because of the enlarged liver and spleen, and the skin of the fetus may be very pliable and covered with coalescing bullae. In recent years, the pathologists have had considerable success in finding the spirocheta pallida in organs of the syphilitic fetus. The diagnosis of syphilis in the dead fetus is frequently of momentous importance. The various diagnostic procedures should include the following: (1) gross examination of the fetus, (2) pathologic study of the viscera, with a careful search for the spirocheta pallida, (3) careful investigation of the family, (4) paternal and fetal Wassermann and Kahn tests, (5) examination of the placenta by a pathologist.

Early Congenital Syphilis

Early congenital syphilis appears a few days to 3 or 4 weeks after birth. In our experience, infants presenting signs of early congenital syphilis at birth, or 2 or 3 days following, almost always succumb to the disease, in spite of treatment. Signs of early congenital syphilis practically always appear during the first 3 months of life, or not at all. The appearance of a syphilitic infant at birth is very suggestive. The child is weak, puny, debilitated, the skin is wrinkled, and there is an "old mannish" expression to the face. Frequently, the child is unable to nurse from the breast; the child is unable to sleep, and cries almost constantly. Very frequently there is a rhinitis, rapidly becoming purulent, which gives rise to "snuffles." As the nasal passages become obstructed, the child is unable to nurse, and loss of weight ensues. Frequently, there are cutaneous and mucous membrane lesions, which, together with the above symptoms should give rise to a strong suspicion of early congenital syphilis. It is a reflection upon the medical profession that a higher per cent of these cases are not recognized early, and properly treated. Clinicians should not have to wait for corroborative serologic evidence in a

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1930.

child or in the parents before starting treatment Many lives would be saved if earlier diagnoses were made and treatment instituted at once

Cutaneous Lesions

The cutaneous eruption of early congenital syphilis closely resembles that of the acquired form This point needs to be emphasized, because most practitioners and students have the idea that the cutaneous manifestations of early congenital syphilis differ widely from those of acquired lues There are several features of early congenital cutaneous manifestations that need to be emphasized First, a marked tendency to involve the palms, soles and genital region, and around the mouth and adjacent cheeks Secondly, the macular or roseolar eruption is less common than in acquired syphilis Third, the maculo-papular eruption is the most common eruption of early congenital syphilis and fourthly, the pemphigoid or bullous syphilide occurs in approximately 10% of cases This, of course, practically never occurs in acquired syphilis The sites of predilection are the palmar and plantar surfaces, the thighs, and buttocks Papular and papulo squamous syphilides are common and as characteristic as in the acquired form of syphilis Around moist surfaces such as the mouth, nares, ano-genital region, these lesions become eroded, with resultant fissuring, which is called rhagades These lesions heal, leaving scars which are practically pathognomonic of congenital syphilis Bullous syphilides are very characteristic They usually appear shortly after birth, but sometimes later. The pellicle breaks after a few hours, and forms a crust, or the skin may remain eroded In our experience, an infant with a bullous syphilide practically never recovers, at least, we have never seen one do so A persistent erythema with scaling of the palms and soles is very suggestive of early congenital syphilis, and should stimulate further search for evidence of the disease In some instances there may be a generalized, mildly exfoliative dermatitis As a general rule, however, the eruption is very similar to that occurring in early acquired syphilis Bullous syphilides must be differentiated from bullous impetigo or impetigo neonatorum The latter condition affects principally the face, neck, and trunk, and almost never the palms and soles early in its course The lesions are less infiltrated In early congenital syphilis, other manifestations of syphilis are not difficult to find

Mucous patches and condylomata occur in about the same frequency as in the acquired form of the disease A persistent rhinitis in a child under 3 months of age, and especially if hemorrhagic, is almost diagnostic of early congenital syphilis This rhinitis is due to mucous patches on the nasal mucous membrane and spirochetes are present in the discharge

Late Cutaneous Lesions

As a general rule, the late cutaneous lesions of congenital syphilis are comparable to the lesions occurring in the course of late acquired syphilis Gummatous lesions are the most common Superficial, serpiginous, nodular lesions are very rare as well as squamous syphilides of the palms and soles Gummatous lesions appear usually near joints, or involve the cranium, and nose They are usually periosteal or osteo-periosteal and may cause considerable destruction Onychia, and paronychia occasionally occur, as well as thinning of the hair of the scalp, eyebrows and eyelashes

Bone Lesions

In general, the lesions of the bones, joints, muscles, and bursae in congenital syphilis are similar to those occurring in the acquired form of the disease There is, however, one exception, and that is osteochondritis, or epiphysitis, which is so characteristic of congenital syphilis Various observers differ as to the frequency of this condition In our experience, it occurs in *about 20% of cases of early congenital syphilis*, and in somewhat less of late congenital syphilis Pain is the predominating symptom manifested by crying day and night, more marked when the child is handled, and causing a functional pseudoparalysis of the lower extremity known as Parrot's pseudoparalysis Frequently, there is a palpable swelling at the epiphyses of the long bones We have been able by routine *x*-ray examination of the long bones to diagnose osteochondritis that was not otherwise apparent *X*-ray examination reveals a thickening and irregularity of the epiphysial line

Periostitis and osteitis occur in 2 to 5% of patients with early congenital syphilis

Visceral Lesions

The heart and liver are frequently and severely involved in early congenital syphilis, and the spleen less frequently From a treatment standpoint the liver presents the most important problem upon which success or failure usually depends

Neurosyphilitic manifestations are extremely difficult to recognize in the young babies The commonest signs are palsies and convulsions

The eye and ear changes are the same as in early acquired syphilis

Late Congenital Syphilis

As in acquired syphilis there is a period of latency in congenital syphilis following the resolution of the early manifestations This period may be from 2 to as long as 30 or more years in duration The longer a child goes without developing late manifestations the less likelihood there is of his so doing However, we have recently seen an untreated woman 48 years of age, present her first attack of interstitial kera-

titis. She had other undoubted stigmata of late congenital syphilis. Many children with late manifestations give no history of earlier signs or symptoms, although some are unrecognized in infancy. Better social service follow-up, combined with routine serologic tests of families in which there is a congenital syphilitic child has led to the recognition of many cases long before late manifestations have appeared. Thirty-five per cent of our patients, during the past 5 years, fall into this group. Because of this fact, the frequency of occurrence of the various manifestations of late congenital syphilis has materially dropped. We believe that this is one of the greatest fields for effective social service work, and should be an integral part of every syphilitic treatment service. The majority of these children range in age from 1 to 6 years, and if the disease is recognized at this time, the state and community are saved a future huge economic and monetary loss.

Chart I presents a summary of the principal signs of late congenital syphilis arranged in order of frequency. A comparison with Stokes'[4] figures shows our percentages to be materially less, with the exception of the blood Wassermann which was positive in 95% of our own cases as compared with 66% of Stokes'. These discrepancies are readily explained by the fact that 75% of our patients were under 10 years of age, and 50% under the age of 6 years. From Stokes' comparative chart, in which no figures are given, about two-thirds of his patients were over 9 years of age. This apparent discrepancy illustrates nicely the tendency of congenital syphilis to heal itself as the age of the individual progresses, due to the gradual increase in immunity. Our lower percentages are also explained by the large number (35%) of children detected in the latent period, between the ages of 1 and 6.

As shown in the chart, the most important manifestations of late congenital syphilis are interstitial keratitis, Hutchinson teeth, bossing of the skull, facies, high-arched palate, sabre shins, scaphoid scapulae, saddle nose, eighth nerve deafness, osteitis, periostitis, osteochondritis, mulberry molars, cutaneous gummata, and visceral lesions.

CHART I.

Chief Signs of Late Congenital Syphilis in Order of Frequency

	Authors'	*Stokes'*
BloodWassermann	95%*	66%*
Interstitial Keratitis	20%	52%
Hutchinson Teeth	18%	32%
Bosses	10%	44%
Facies	8%	21%
High Arched Palate	8%	19%
Sabre Shins	7%	43%
Mentally Defective	6%	25%
Neurosyphilis	6%	26%
Scaploid Scapulae	5%	20%
Saddle Nose	4%	30%
Nerve Deafness	4%	10%
Bilateral Hydrarthrosis	3%	3%

* First blood Wassermanns only.

The Hutchinsonian triad is composed of interstitial keratitis, characteristic teeth, and eighth nerve deafness. Each manifestation has been regarded as pathognomonic of congenital lues although in recent years some doubt has been expressed regarding the last-named member of the triad. Seldom do these three signs occur together in the same individual. The first two are frequently present together.

Interstitial keratitis is the most common and distressing manifestation of late congenital syphilis. Most children lose from 1 month to 3 years of school, and about 25% are permanently handicapped economically. The vast majority of cases begin between the ages of 5 and 16. The first symptom is a mild ciliary congestion followed by a faint, grayish infiltrate near the centre, or at times the periphery of the cornea. The deposit spreads until the entire cornea is involved and has a cloudy appearance. New blood-vessels grow out from the ciliary vessels and the deposit becomes pinkish, giving rise to the term "salmon patch." The patient complains first of smarting, followed by distressing photophobia and lacrymation. The process may continue for a few weeks or several months before healing occurs. If mild, the visual impairment is slight, but if severe or recurrences take place the impairment may amount to total blindness. The process usually begins in one eye, and in a few days or weeks, and exceptionally after several years, the other eye may become involved.

Iritis frequently, but not invariably, accompanies interstitial keratitis. Scleritis, choroiditis, and retinitis may also occur.

Next to interstitial keratitis the teeth are of greatest importance from a diagnostic standpoint. The first or milk teeth are usually late in arriving, undergo early necrosis and fall out several weeks or months before the usual time. The second or permanent teeth may be late in appearing. The changes, occurring only in the upper central incisors of the permanent teeth, are characteristic. They are known as Hutchinson's teeth. It is well to bear in mind the description of Jonathan Hutchinson,[5] as given in his book on syphilis after a lifetime of medical practice. "The more closely we keep to the peculiarities displayed by the upper central incisors, the less will be our risk of error. All the other teeth are liable to lead us astray. If the upper central incisors are dwarfed, too short and too narrow, and if they display a single central crest in their free edge, the diagnosis of syphilis is almost certain. If the crest is present, and the dwarfing absent, or if the peculiar form of dwarfing be present without any conspicuous

crest, the diagnosis may still be made with much confidence Usually, the conditions are symmetrical, but now and then they are notably one-sided" This description coincides with our observations very closely He points out concisely that the dwarfing may be absent, or the crest or notch may be absent In our experience the two most important factors are First, narrowing of the tooth from the gum margin towards the free edge, and second, thickening of the tooth anterio posterially The notching may or may not be present in one or both teeth If the upper central incisors are unerupted and this frequently occurs between the ages of 4 and 6, the characteristic malformations can be shown by means of the *x*-ray, as Stokes and Gardner have pointed out Fournier's mulberry molars are also characteristic, although not pathognomonic The six-year molars undergo necrosis on the surface, and with the serrations around the border, the appearance is that of a mulberry All of the other teeth, especially the lateral incisors, may be poorly spaced, show aplasic changes and undergo early necrosis We have never believed that the tubercle of Carabelli[6] was diagnostic

Eighth nerve deafness is the third member of Hutchinson's triad It occurred in only 4% of our series, probably because such a large percentage of our cases were detected before the sixth year of life The onset of this condition is usually between the 9th and 15th years of life

Bone changes are among the most important marks of late congenital syphilis They are the result of osteitis, and periostitis in the earlier months of life, producing thickening and roughening, especially of the shaft of the long bones The tibiae and clavicles are the most commonly affected The sabre tibia derives its name from an apparent anterior bowing which is due to a fusiform thickening, usually of the middle third of the shaft The sharp anterior edge as well as the flat medial surface of the tibia is rounded *X*-ray examination should differentiate the anterior bowing of rickets from the periosteal thickening of congenital syphilis Enlargement of the frontal and parietal bosses has some significance Bilateral hydrarthrosis of the knee joints known as Clutton's joints is almost pathognomonic In addition to the actual bone involvement there are certain developmental changes such as high arched palate, scaphoid scapula venous ectasia of the scalp and the facies which are very suggestive To the experienced eye, the facies are extremely valuable in picking out suspicious cases and in focusing attention on a possible congenital syphilis The facies, or facial expression, is the impression produced on the examiner by a combination of syphilides and developmental dystrophies including corneal scars depressed nasal bridge, increased breadth and height of the forehead, upward and outward flare of the nostrils, and in addition a dreamy tired, apathetic expression

CHART II

Results of Intensive Combined Sulpharsphenamine and Bismuth Therapy

Patients treated	129
Patients died	2
Patients lost through change of residence	22
Patients treated with malaria	5
Patients negative more than 1 year	19
Patients negative more than 6 months	14
Patients negative less than 6 months	10

Visceral lesions in late congenital syphilis are not as common as one would expect from the overwhelming number of organisms present in all organs at birth The child survives the intense infection and the resulting fibrosis We believe that a congenital syphilitic child that has survived the first year of the disease has a much higher resistance to the infection than an adult with an acquired infection of the same duration

Neurosyphilis in our series occurred in 6% of the cases Juvenile paresis is the predominant manifestation, and juvenile tabes one of the rarest of clinical manifestations A routine spinal fluid examination is absolutely essential in spite of negative blood serology

Treatment of Congenital Syphilis

There are certain general principles regarding familial syphilis that should be mentioned before considering the treatment of the child, namely

1 Every pregnant woman should have a routine blood Wassermann and Kahn test early in pregnancy

2 Adequate treatment of a pregnant woman with syphilis should be given from the earliest possible moment Very few syphilitic children are born from adequately treated mothers

3 After the third month of pregnancy, the dosage of the drugs employed should be approximately two thirds the adult dose

4 Multiparas, who are serologically positive, or who are known to have had syphilis and have become serologically negative, should have at least one full course of treatment during pregnancy

In considering the treatment of the child we will confine our remarks to our own experience because time does not permit an exposition of all the drugs and systems of treatment employed by various workers in this field We will admit that, prior to 1925, we had a pessimistic attitude toward the effectiveness and curability of congenital syphilis by any system of treatment Our attitude has changed considerably since then to one of restrained optimism The success of any system of treatment depends upon the following factors

1 Early diagnosis and the prompt institution of treatment
2 Adequacy of treatment with effective drugs
3 Persistent therapeutic effort in spite of serology

4. Short rest intervals.
5. Routine spinal fluid examination.
6. Serologic and clinical check-ups over a long period of years.

From our experience with arsphenamine, neoarsphenamine, and sulpharsphenamine, we believe that the latter is the drug of choice and since 1925, have employed it in every case. We have had only one treatment accident of any account, namely, a moderate exfoliative dermatitis. Since starting the use of sulpharsphenamine intramuscularly or subcutaneously, we have had more cooperation from the parents and fewer absences from treatment than ever before. The dosages employed have been as follows:

First 4 weeks of life	.05 grams
1 to 3 months old	.1 grams
3 to 6 months old	.1 to .15 grams
6 to 12 months old	.15 grams
1 to 2 years old	.15 to .2 grams
2 to 3 years old	.2 grams
3 to 6 years old	.2 to .3 grams

Frequently, we have noted that subcutaneous injection, although more painful at the moment, produces less after-pain than intramuscular injection.

During the past 5 years, bismuth has almost entirely supplanted mercury in our system of treatment. We heartily agree with Schamberg and Wright,[7] and more recently Wright,[8,9] in the effectiveness of bismuth over mercury in the treatment of congenital syphilis. In view of this it hardly seems rational to continue the use of mercury when active manifestations are present. We have recently limited the use of mercury to mercurial inunctions over long periods of time in children who are serologically negative, or who cannot come to the clinic regularly. A word of warning is necessary regarding the preparation of bismuth employed. The physician should know the content of bismuth metal in each ampule or cubic centimeter and the dose should be computed on a basis of 100 mgr. of bismuth metal to the average adult dose. The dosages of bismuth metal employed are as follows:

First 4 weeks of life	.02 grams
1 to 3 months old	.03 grams
3 to 12 months old	.05 grams
After 1 year according to weight up to	.1 grams

Iodides are seldom of value in congenital syphilis. They should be used in late visceral lesions, keratitis, neurosyphilis, and osseous lesions.

We believe absolutely in the value of combined therapy, that is, the simultaneous use of sulpharsphenamine and bismuth until there are no active symptoms, or until the blood serology is persistently negative. After this, treatment need not be so intensive, but should be continued with longer rest intervals for several years. In cases that are Wassermann-fast after 6 or 8 courses of treatment, periodic courses of bismuth over long periods of time are indicated. It is surprising how many of them finally become negative.

A few special problems in the treatment of congenital syphilis should be mentioned.

1. In active syphilis of the newborn with enlarged liver and spleen, it is best to begin treatment with bismuth for at least 6 to 8 weeks. Arsphenamine should be used cautiously or not at all.

2. Interstitial keratitis requires the cooperation of the ophthalmologist and the syphilologist. Intensive combined treatment is indicated from the beginning with no rest intervals until the disease is thoroughly controlled. In 30 consecutive cases of interstitial keratitis we have not had a single failure nor a relapse, nor has the second eye become involved after therapy was started. The vast improvement in the response of interstitial keratitis to intensive, combined sulpharsphenamine and bismuth therapy is the most encouraging development in the treatment of congenital syphilis.

3. We have treated 5 cases of juvenile paresis with malaria. The result was excellent in 3. Our impression is that the cases must be gotten early before too much parenchymatous destruction has taken place, in order to get a good result.

Our routine system treatment consists of 8 subcutaneous or intramuscular injections of sulpharsphenamine combined with bismuth, followed by 10 bismuth injections, then 1 month rest, and a repetition of the first course. At least 3 or 4 such courses are given before lengthening the rest interval or discontinuing the combined method of administration. Providing the spinal fluid is negative, we give as many as 6 to 8 courses and if the blood serology is still positive, long courses of bismuth are given with rest intervals of 3 to 6 months between courses.

OUR NEWS DEPARTMENT

When each JOURNAL is completed the editors wonder how the next fortnight will develop enough material to make a news department of respectable size, but the medical societies of New York State are active, and abundant records of their work are always forthcoming The news department of this issue fills ten pages

It is gratifying that the leaders in the county medical societies are overcoming their inferior complexes and are sending records in increasing amounts But there is yet room for improvement Only one-half of the county medical societies sent records of their activities during the past year, and the list of those who did not send records includes some of the largest and most active of all the societies However, the indications of improvement are gratifying, and the secretaries are acquiring a proper sense of the value of their reports

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—NO. 13

As the year advances, the study of the medical activities of the counties gives a better understanding of the existing medical relationships. It brings into relief certain outstanding county societies. Since human nature is about the same everywhere, one wonders why there is a difference until a little closer study shows that it is simply the result of leadership,—true leadership that inspires men to follow. Partly to illustrate how an activity initiated by leadership is carried on by the entire profession, and partly to tell the profession of what has been done in one of the counties of the State, I shall comment on the observations of a two-day visit in Tioga County.

On November 24th your President had the privilege of speaking to the medical profession of Tioga County and vicinity on the occasion of the opening of the Tioga County General Hospital, and on the following day of speaking to the lay organizations and citizens of the county.

Three thousand, two hundred people, which is eight per cent of the population of the county, contributed the money to build the seventy-bed hospital. It is a four-story fireproof building, that for detail of planning for efficient and economic administration, and for perfection of equipment and for modernity, I have not seen surpassed.

This hospital is located in a county having twenty-six thousand population.

In the first ten days after opening the hospital, there were fifty-one admissions and nine of them major surgical operations.

The striking thing about the hospital is its economy in non-essentials and its remarkable planning for ease of administration. It is intended to administer this hospital without financial deficits. While its obligation is to give the best professional service to the end that the patient may be restored to health quickly and surely, there is no intention of otherwise making it a dispenser of luxury in non-medical service. For meeting the expense of caring for the indigent, the Welfare Commissioner of the County will be depended upon, and since he is one of the Board of Directors, it seems likely that the hospital will be paid for its care of all the indigent entitled to it. This hospital, both in its professional and loyal general support, is one of the finest examples of civic effort and a contribution to the solution of the great problems now interesting the leaders of medicine and the leaders of public health opinion.

To go back a little way in the medical history of Tioga, about six years ago the county was chosen as a demonstration county for rural prenatal care. After the matter had been considered and unanimously approved by the County Medical Society, the demonstration was financed by the Shepard-Towner funds. There were two nurses at first and later four. The result of the work was highly satisfactory to the physicians and to the public. Its educational effect was apparent in teaching expectant mothers to seek earlier and regular prenatal care. At the end of two years, the County Medical Society and the lay organizations jointly applied to the Board of Supervisors for an appropriation to carry on the work and for the creation of a Public Health Committee. The appropriation was made,—the State paying half. The Public Health Committee was established, made up of two supervisors, three physicians, two from the lay health organizations, and one citizen. Two nurses are employed at present, each having thirteen thousand people. A third one is under consideration.

The present cooperating factors in health work in this county are the Tioga County Medical Society, the Tioga County General Hospital, the Tioga County Public Health Committee, the State Charities Aid Association, and the State Department of Health. These organizations, each doing something that the other cannot and working cooperatively, stimulated by the civic health spirit that has grown in that county as the result of their own accomplishments, become an illustration of the value of the right kind of public relations. It seems to be an answer to the problems of public health and medical care.

The fact that a county has enough civic pride to initiate an effort to meet health problems, shows that it can be done elsewhere or anywhere. There were just as many difficulties to overcome in the rural county with a small population and no great wealth, as in any other county in this State. If what has been done by the local profession who created public opinion, aroused its interest, and gave it leadership were done all over the State, there would be no need to waste time on a discussion of State Medicine, socialization of medicine, interference with private practice or economic conditions.

I do not know of any better illustration of how to essentially meet the problems confronting medicine today than has been done in Tioga County. This is a simple story of fact, I am relating, partly for its practical interest,—(no one in Tioga seems to think it unusual, however),—and partly because the local profession has access now to a hospital splendidly equipped in which to do their work and receive in return the benefit of continuous education in their own environment, and with the further result of advancing community standards of practice.

There are other counties in the State with a conception of how to meet present-day problems of medicine and who have advanced the essential principle of cooperative relationship of health influences, guided by medical leadership. The only reason that these are not discussed is lack of space at present.

WILLIAM H. ROSS, M. D.

NINETEEN THIRTY-ONE

The organization of the Medical Society of the State of New York, which was consummated just a quarter of a century ago, is the standard form of nearly every State Medical Society of the United States. Even the standing committees of the several State Societies perform similar duties, although they have a diversity of names; and the leaders all over the country are actuated by the same high motives of service to their brother practitioners and to the public.

The principal work of past years has been to arouse an interest in the practice of those forms of medicine which depend on the collective action of individual doctors. But since the movement has started, the same inertia which formerly impelled doctors to stand still, will now carry them forward in the support of the policies of the societies.

The year 1931 opens auspiciously for the medical profession, not only of New York State, but also of the entire nation.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Consolidation:—The union of the Medical Society of the State of New York, and the New York State Medical Association was consummated on December 9, 1905, by a Court order, and the Journal of January 1906 devotes considerable space to the consolidation. It is surprising how soon a knowledge of bitter disputes fades from memory, and it was therefore with real difficulty that the facts regarding the formation of the rival societies were obtained.

The Medical Society of the State of New York was formed in 1807, as the result of a law passed on April 4, 1806, authorizing the formation of medical societies of the counties and of the State, for the purpose of licensing practitioners of medicine.

The State Medical Society adopted a "New Code" of ethics in 1882, one paragraph of which read:—

"II. Rules governing consultations.

"Members of the Medical Society of the State of New York, and of the medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine. Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the demands of humanity."

The "legal practitioners" to which this section referred were Eclectics and Homeopaths, neither of whom were recognized by the American Medical Association; and the State Society therefore ceased to be affiliated with the A.M.A.

Section 1 of Article IV of the code of ethics of the American Medical Association, which conflicted with the New York code, appeared as follows in the editions of 1875 and 1899—

"A regular medical education furnishes the early presumptive evidence of professional abilities and requirements and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations, the good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner who has a license to practice from some medical board of known and acknowledged respectability recognized by the American Medical Association and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship or his aid refused in consultation when it is requested by the patient. But no one can be considered as a regular practitioner or a fit associate in consultation whose practice is based on an exclusive degree, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, or organic chemistry."

When the State Medical "Society" met on February 5, 1884, about one hndred members, failing to secure a vote to rescind the objectionable paragraph, seceded, and on the next day they formed the Association. The reports of the discussion at the organization meeting seem humorous today with their abuse and their predictions of calamity; but strangely, the two systems of medicine were not mentioned.

The two State organizations existed side by side for twenty years and many physicians belonged to both. When the two societies united on December 9, 1895, the Association accepted the "New Code" of Ethics, and the Society adopted the modern form of organization of the Association. Thus each side won, and both sides forgot what the trouble had been

The present codes of the A. M. A. and that of New York both omit all reference to "Regular practitioners and schools of medicine.

MEDICAL PROGRESS

Special Fields in Physical Therapy.—In a report of the Committee of Standardization of Physical Therapeutic Measures of the American Physical Therapy Association, William Benham Snow states that the use of physical therapy applied for the relief of human suffering and disease has not been properly appreciated by the medical profession at large. The Council on Physical Therapy have been disposed to place physical therapy in the rôle of an adjunct measure, which it is not. As appears in the triangle—medicine, surgery and physical therapy—physical therapy is placed at the base of the triangle, supporting the other lines. This is where it belongs. There are many indications for its employment that should be given proper consideration. The *treatment of focal infection* by diathermy, light and *x*-rays has advanced to a degree of practical accomplishment that has established its importance. The time has passed for operations on the *sinuses,* because surgical intervention is unnecessary except in cases that have been so neglected that necrotic changes have taken place in the bone, which the *x*-rays will differentiate. Equally certain is the result of treatment for *gallbladder infection.* There are few cases of this type of infection that require operation under the present possibilities of the complete relief afforded by diathermy. In certain appendix cases—those upon which the conscientious surgeon hesitates to operate—radiant light and heat properly employed, diathermy and *x*-rays bring about a prompt recovery. With the present improved methods of operation—desiccation, coagulation, the use of *x*-rays and diathermy—there are few *tonsils* that cannot be put in order without removal and the patient so relieved of any danger of focal infection. The most advanced cases of *Graves' syndrome,* in which the surgeon will not operate, can be restored to the normal by skillful treatment with physical therapy. *Diabetes* in the early stages can be readily cured by physical therapy applied to the dilated splanchnic area. In the treatment of *hypertension,* autocondensation and mechanical vibration play a very important part. There are few patients with *arthritis* in the early stages that cannot be fully restored by physical therapy. *Bronchitis, pleurisy, pneumonia,* and *asthma* are so amenable to this form of therapy that few additional measures need be considered in order to abort these diseases in their early stages. In *poliomyelitis* no other method offers the prospect of prompt relief and early cure after paralysis that the static current and radiant light and heat do. The pelvic diseases of men and women are markedly benefited by physical modalities. Mechanical vibration in the treatment of cardiovascular, pulmonary, gastric, pelvic, gastroenteric and other conditions will accomplish much that cannot be attained by other measures.—*Physical Therapeutics,* November, 1930, xlviii, 11.

Achlorhydria and Anemia in Advancing Years.—Daniel T. Davis and T. G. Illtyd James examined 100 persons over 60 years of age and in normal health to determine their response with respect to acid gastric secretion. The most striking departure from normal was the high frequency of achlorhydria—32 per cent of all cases. The fact that achlorhydria was found in this large percentage of healthy persons minimizes its diagnostic value in carcinoma of the stomach. Of the 32 cases 27 were submitted to histamine stimulation a few days after the ordinary gastric examination. In 13 of these cases there was hydrochloric secretion after the injection of histamine, while in 14 cases achlorhydria persisted, showing that in these cases there was true achlorhydria. Thus the incidence of true hydrochlorhydria was about 15 per cent. A slight degree of anemia was found more frequently in cases showing a true hydrochlorhydria than in those showing a normal acid secretion. Anemia was found to be more common in cases showing a diminished pepsin secretion than in those showing a good secretion of pepsin. It is well known that changes in the mucous membrane of the tongue are found in pernicious anemia and that soreness of the tongue is often one of the symptoms, sometimes the earliest, observed by the patient. Of the 68 cases in this series that showed some secretion of acid, a smooth tongue was found in only two, but was present in seven of the 32 showing achlorhydria. Of the seven cases showing atrophic changes in the tongue four were in the true hydrochlorhydria group. A smooth tongue is therefore found more often in cases showing a deficient gastric secretion than in cases with a normal secretion; this emphasizes the fact that atrophy of the mucous membrane of the tongue and an abnormal or deficient gastric secretion may occur together.—*The Lancet,* October 25, 1930, ccxix, 5591.

The Antagonistic Action of Liver and Spleen.—F. Högler, in the *Klinische Wochenschrift* of November 1, 1930, points out, on the basis of three illustrative cases, certain phenomena suggesting that in the pathogenesis of pernicious anemia and of erythremia the leading rôle is played by the antagonistic action between liver and spleen. The liver appears to produce a substance which increases the number of red cells circulating in the blood stream, while the spleen, on the other hand

seems to elaborate one that decreases their number. Thus in the normal organism the constancy of the red cell count would rest on a finely adjusted regulatory mechanism between these organs. It is impossible as yet to determine whether the effect of the hypothetical substances consists more in an increase or in a restraint of erythropoiesis, or in a restraint or increase of hemolysis, and hence in a lengthening or shortening of the life span of the red cells. It can be readily understood that these relations are not revealed so clearly in the normal organism by experimental splenectomy or administration of liver or spleen, since here the antagonistic regulatory activity begins at once, its intensity varying in the individual case according to the degree of formation of accessory spleens. Strong support is given to this theory of antagonistic action by the fact that in most cases of pernicious anemia the red cell count is restored to normal or even supernormal by administration of liver and the further fact that in erythremia the enormously increased red cell count is reduced to normal or subnormal values by administration of spleen. Finally the circumstance that in pernicious anemia we can increase the red cell count by splenectomy in so far as this is not thwarted by new growth of accessory splenic tissue, and that administration of liver in splenectomized cases of pernicious anemia can transform these into typical erythremia, offers further evidence in the same direction.

Relationship between Measles and Whooping-Cough.—Wladimir Mikulowski points out the frequency with which a whooping-cough epidemic comes on the heels of an epidemic of measles, suggesting that it is in reality a recurrence caused by concealed measles. It is significant that most cases of whooping-cough occur in the months of March, April, and May, which are the same months in which measles prevails. The statistics concerning region, age, and social status, as well as atmospheric conditions, which exert an influence on measles infection and mortality in children under five resemble those of whooping-cough. In large cities a measles epidemic is as a rule accompanied by an epidemic of whooping-cough. Clinical observation shows that in those children who have been having whooping-cough an infection with measles causes a recurrence of whooping-cough, in the form either of a new pulmonary focus or of a flaring up of old anatomic changes or lung complications. The symptoms of a whooping-cough focus that has been rendered acute by measles may appear either at the very outset of the measles or at the close of an attack of the latter. In the first case, measles in the incubation stage often begins with lung symptoms which cause the child with whooping-cough to be taken back to the hospital. When such a child returns during a measles epidemic the physician should look into the cause of the recurrence. If he cannot exclude the possibility of measles he must regard the child as a measles suspect. If such a child dies all the children in that ward should be isolated as if they had been exposed to measles. In the second case, the old lung focus in the child with whooping-cough becomes acute again after an attack of measles and often causes complications. The cough breaks out with fresh intensity and suggests a new case of whooping-cough. It is difficult to determine whether measles with whooping-cough complications or whooping-cough with measles complications predominates as a cause of eventual death. This close epidemic and clinical affinity explains why the morbidity statistics of the two infections show almost the same figure and also why the mortality figures are often nearly the same.—*Schweizerische medizinische Wochenschrift*, October 18, 1930.

New Treatment of Morphine Addiction.—M. Sakel says that for two years he has been treating the abstinence symptoms in morphine addiction with rather large doses of insulin. In order to check these symptoms of abrupt withdrawal he gives the patient during the first 6-8 days doses of insulin amounting to 80 units in 24 hours without glucose. The insulin treatment is instituted as soon as the abstinence symptoms appear. Thus far he has used the method in 15 cases, and in all he succeeded in cutting short both psychic and somatic symptoms, such for example as vomiting, diarrhea, and refusal to eat. In the first cases thus treated (1929) he administered glucose at the same time, fearing hypoglycemic shock. He also gave small amounts of barbituric acid, on the basis of experience at the Charcow Clinic, which had demonstrated that animals which had received this preliminary treatment tolerated doses of insulin many times as large as animals not so treated. Gradually he observed, however, that the effect of insulin was much greater without administration of glucose, and that it was altogether exceptional for any untoward hypoglycemic symptoms to appear. Most of the individuals treated were confirmed addicts who had already been treated in many institutions. In all the cases not only did he have success with minimum trouble, but in addition nearly all the patients had begun to take on weight by the end of the first week. They could sleep with scarcely more than the customary medication, and only in a few cases was any other sedative necessary. The therapeutic results obtained were naturally limited to those related to abstinence symptoms; permanent cure of morphine addiction is of course left for after-treatment in the form of psychic influence, as always.—*Deutsche medizinische Wochenschrift*, October 17, 1930.

LEGAL

HUSBAND AND WIFE—COURT'S REFUSAL TO ANNUL MARRIAGE ON GROUND OF EPILEPSY

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

The Court of Appeals of this State recently handed down an extremely interesting decision in an action brought by a husband against his wife, seeking an annulment of their marriage on the ground that the wife was incapable of entering into the marriage state as she was suffering from epilepsy and fraudulently concealed that fact from her husband. Judgment was rendered in favor of the defendant in the Supreme Court, from which judgment the plaintiff appealed to the Appellate Division. That court reversed the judgment of the lower court and directed judgment in favor of the plaintiff, annulling the marriage. From the decision of the Appellate Division the defendant appealed to the Court of Appeals. The case arose on the following state of facts:

The defendant wife was thirty-five years of age at the time of her marriage. For fifteen years prior to her marriage she had been a teacher in the public schools, and the official records of the Board of Education disclosed that her attendance had been very regular, and the principal of her school testified that she was considered an able teacher.

During the period of courtship which lasted for many months prior to the marriage, the plaintiff saw the defendant many times every week and finally the parties were married. They lived together as man and wife, the defendant fulfilling all the obligations, duties or privileges usually accompanying that position. The wife became pregnant some four months following the marriage, and at that time resigned her position as a school teacher. About that time the wife lost her engagement ring. The loss of the ring was attended by great excitement. In the language of the court: "The wife became unconscious, fell to the floor, was put to bed, neighbors came in, relatives were sent for, even the policeman. It is said that she had a fit of some kind, that her eyes rolled, that she foamed at the mouth. Apparently there was no privacy. Dr. X had been treating the wife, or consulting with her during the previous months of pregnancy. He was sent for. Another doctor, Dr. Y, came in. The husband again describes the scene: 'When I came back I found Dr. Y attending to her, and just as soon as I entered the apartment, Dr. X came running in from the outside, and he said to Dr. Y, "She is my patient." And during that time they pulled her into the bedroom—here was the kitchen and there was the bedroom, and they pulled her right on, and Dr. X said, "She is my patient, leave her alone, and I am taking care of her." Dr. Y went away, and Dr. X went into the bedroom, took her mother and sister Mollie into the bedroom, shut the bedroom door, put a curtain on top of the bedroom and he kept—he said nobody should enter the bedroom, and he kept everybody out. Then a little later—pardon me, then a little later, Dr. X came out from the bedroom, and he rushed right out'."

Shortly after this the wife had double pneumonia, and later gave premature birth to a child which lived less than a month. About two months after the birth of this child, the husband claims that while they were eating breakfast the wife got up from the table, went out of the room into her bedroom, where she fell on the floor, blood coming from her mouth, her eyes bulging; she was unconscious.

A physician testified that the husband with his lawyer called upon him, and he told them he thought the attacks were epilepsy. Thereupon the husband left the wife, and brought this action to annul the marriage on the ground that the wife was incapable of entering into the marriage state, as she was suffering from epilepsy, and that she fraudulently concealed the fact.

The court first took up the proposition as to whether there had been any fraudulent concealment by the defendant, if at the time of the marriage she was suffering from epilepsy, and in finding that there was no such evidence the court said:

"Conceding that the spells in November of 1926 and April of 1927 were epileptic seizures, there is no probative evidence to show that the wife ever had such attacks before. Two school children were called by the plaintiff to prove that as a teacher she occasionally held her head in her hand as though she were tired, and a workman said that once when hanging curtains, the defendant fell to the floor. Hypothetical questions based upon the testimony of the husband and the neighbors were asked of experts who gave it as their opinion that the attacks in November and in April must have been epileptic spells.

Upon a physical examination these same doctors could find nothing the matter with the defendant A gynecologist from the Z Hospital, consulting obstetrician, said that the attacks were due to a toxemia frequently occurring during pregnancy and for several weeks thereafter. There is no evidence in the case sufficient to support a finding that the defendant had epilepsy prior to June, 1926. Neither does the proof show that a person having an epileptic fit must always have suffered from epilepsy. On the contrary, there is evidence from the plaintiff's expert that it may start at thirty-five years of age. Assuming, therefore, that the defendant had epileptic seizures in October, and that in April, as above related, six months and more after she was married, there is no credible evidence to show that she had any such attacks prior to marriage or knew that she had epilepsy. A Mr B, a stranger whom the defendant had never met, testified that after the defendant was put to bed on the November occasion, he asked her how she felt and how long she had been sick, 'with the sickness,' and that she replied 'quite a time—from childhood.' Such a statement from such a source without any corroborating background was at most insufficient to justify the reversal of the Special Term. Judgment in favor of the plaintiff on the ground of the defendant's fraudulent concealment was, therefore, without evidential support, and must be reversed."

The court then went on to discuss whether epilepsy in and of itself would justify the annulment of a marriage. Section 7 of the Domestic Relations Law provides that a marriage is void from the time its nullity is declared by a court of competent jurisdiction if either party thereto is incapable of entering into the marriage state from physical cause, or if either party consents to such marriage by reason of fraud; for example, it has been held that a person suffering from a venereal disease is incapable of entering into the marriage state. In distinguishing that rule from the facts in the case at bar the court said:

"Epilepsy, however, is not to be classed with any such loathsome contagious disease. The record in this case is barren of any evidence as to the nature of epilepsy or its general effect upon the physical or mental capacity of the person afflicted. Medical treatises inform us that it is a term applied generally to a nervous disorder characterized by a fit of sudden loss of consciousness attended with convulsions. There may, however, exist manifestations of epilepsy much less marked than this, equally characteristic of the disease, while on the other hand, many other attacks of a convulsive nature have the term 'epileptic' applied to them. In some persons the epileptic fit may only occur once in a lifetime or once in the course of many years. (Encyclopædia Britannica, 'Epilepsy.') No incapacity from becoming a wife or performing the functions of the married state necessarily results from epilepsy. The general health and bodily vigor may remain unimpaired.

"Epilepsy, in and of itself, is no ground for the annulment of a marriage in this State. There must be something more than a mere fit or a spell of 'epilepsy' The nature of the disorder may have progressed to such a degree as to be extremely dangerous for the person to marry or to have sexual relations. Concealment of such a condition might amount to a fraud, as it is almost impossible to conceive of its success without some intentional deception or disguise.

"Shall we say, however, that any person subject to epilepsy, or to fainting spells, or to bad temper, bordering on insanity, is incapable of marrying? While the law books may treat marriage as a civil contract, yet it is a contract which the public is interested in preserving. The fraud which may dissolve the marriage tie must relate to something vital. Mere nondisclosure as to birth, social position, fortune, good health and temperament cannot vitiate the marriage contract. The man and woman who marry take each other for better or worse, richer or poorer, to cherish in sickness or in health. If this be old-fashioned according to some moderns, it is still the hope and joy of the pledged loyalty. The law of this State affords no relief to subsequent disappointment. Sickness and misfortune are common to mankind and must be borne with courage and resignation. Most people have something to contend with."

The court then went on to point out (citing a Connecticut case) that some States have provided by statute that no man or woman, either of whom is epileptic, imbecile or feeble-minded, shall intermarry or live together as husband and wife when the woman is under forty-five years of age. Other States, Virginia for example, have provided for sexual sterilization of inmates of institutions supported by the State, who shall be found to be afflicted with an hereditary form of insanity or imbecility. The constitutionality of the Virginia statute in that respect was challenged, but was upheld by the Supreme Court of the United States. After discussing these various statutes of other States already referred to, the court said:

"In the absence of some such legislation in this State, the courts are not justified in establishing a system of eugenics. We would be trespassing upon very delicate and dangerous ground indeed, should we judges, fallible like other men, undertake to say who should and should not marry. It is time enough for the courts to act when it is proved that one of the parties to a marriage was at the time incapacitated from entering into the marriage state by reason of physical deformities or diseases."

DEATH CLAIMED DUE TO NEGLIGENCE IN CÆSARIAN SECTION

In this case the patient consulted the defendant physician who specialized in gynecology and obstetrics. Based upon the examination and history of the patient, it was determined that she was about six weeks pregnant.

Arrangements were made for pre-natal care, confinement, delivery and aftercare. Pursuant to instructions, the patient called at stated intervals for examination by the attending physician. Some time after the first examination, the doctor observed that the patient had a contracted pelvis. She was told at that time and subsequently that it might be necessary to perform a caesarian section, but that nothing could be done about it at that time.

In due course the doctor was notified that the patient was in labor. She had last been seen about four days previously. Pursuant to instructions, the patient was immediately taken to a hospital where she was examined early in the morning by the attending physician who found four fingers dilatation. She was left in bed and instructions given to call the attending physician when necessary. Two hours later the doctor returned to the hospital and found complete dilatation but no advancement of the head. The head was found to be in L. O. P. position.

The husband was then notified that it would be necessary to perform a caesarian section, to which he verbally consented, and the patient was sent to the operating room, prepared and anæsthetized, the customary incision was made and the patient delivered of a living child. The afterbirth was also removed. The abdomen was then closed and the patient put to bed. She recovered from the anæsthesia in due course. She was seen daily by the attending physician during the following week, at which time the wound was healing nicely and the patient was in excellent condition.

Due to illness in the attending physician's family, it was necessary that he leave the jurisdiction and accordingly the doctor arranged with the patient that the usual aftercare would be administered by the house physician and that for any unusual developments the chief obstetrician of the hospital would be called. Both mother and child were in good condition at that time and consented to the termination of the relationship between the patient and the physician. The physician never saw the patient thereafter.

Three days later the patient advised the house physician that she had difficulty in breathing and before anything could be done she became cold and clammy, her pulse became imperceptible and she went into a semi-coma. The chief obstetrician was immediately called but before he could arrive the patient died. During the interval before the chief obstetrician called, adrenaline and caffein-sodium benzoate were administered. Approximately three hours before the patient died she had been seen by the house physician and appeared to be in good condition.

The caue of death was thrombosis of the iliac vessel.

Some six months thereafter an action was commenced by the patient's administrator against the first attending physician and the chief obstetrician of the hospital, charging first, that he performed an operation without consent; second, that he did not give the patient the proper opportunity to advance sufficiently in labor to have a normal delivery; and third, abandonment, and fourth, negligent aftercare. The action duly came on for trial and at the close of the plaintiff's case, the plaintiff having failed to establish a prima facie case in law, the complaint was dismissed, thus terminating the action in favor of the defendant physician without making it necessary for defendant to introduce any testimony.

DEATH OF CHILD ALLEGED TO HAVE BEEN CAUSED BY DOCTOR'S NEGLIGENCE

In this case the defendant doctor was called to the residence of a family where he was asked by the mother of a five-month-old child whether it would be all right if she were to take the baby to the home of her relatives over Christmas, in a town about twenty-five miles away.

The doctor upon examining the baby found her to be active and generally in good condition, with normal temperature and all physical signs negative with the exception of snuffles. The doctor told the mother that if it was a warm day and the baby was wrapped well and taken in a closed car, he could see no harm in taking the child on this trip.

About 6 o'clock on Christmas morning, the doctor received a telephone message from the mother saying that the child was acting queerly and insisting that he call at the home of these relatives to examine the baby. He advised that they call a local doctor, but the parents were in-

sistent and he consented to make the trip. Upon arrival he found the baby in a very cold room and it was necessary for him to take the child into the kitchen so that it would be warm enough to examine her.

He learned that the parents instead of following his instructions had waited until the evening to make the trip instead of during the day. Upon examination the baby appeared acutely ill, pale and somewhat toxic. Her temperature was 103.8; pulse was extremely rapid but of good quality. There were symptoms of bronchial pneumonia in the chest. The abdomen was extended. There was no rigidity and no masses. The doctor told the parents that as they were so far away from his office and as the baby was too sick to be moved, he could not be responsible for the care of the baby and that they should call upon some local physician, and he assisted in calling and arranging for such physician. By way of treatment until the other doctor should arrive, the defendant doctor directed that they keep the child near the fire so that she would be warm and to apply warm applications to the abdomen to reduce the distension and to give the child a small quantity of whiskey. As there was a woman present who said that she was a trained nurse the defendant left the baby in her care and rendered no further treatment in this case.

The second doctor arrived within a short time and found the baby again in a cold room, in a very serious condition. He examined the child with a stethoscope and he likewise concluded that the child was suffering from bronchial pneumonia. He caused a mustard plaster to be prepared, whiskey to be given to the child and administered a hypodermic of digitalis, but in a very short time the child died.

The child's father brought an administrator's action against the first doctor, alleging that due to the negligent treatment rendered this child, the death of the baby was caused, for which large damages were demanded.

The case finally appeared upon the calendar for trial. The defendant appeared in court with all his witnesses, ready to try the case, but because of the failure of the plaintiff to appear the case was dismissed and judgment entered in favor of the defendant.

ALLEGED NEGLIGENT TREATMENT OF MASTOID WOUND

In this case a parent brought a child of five years of age to an ear specialist, complaining of pain in his right ear. The doctor examined him and diagnosed the ailment as acute mastoiditis, and caused an *x*-ray to be taken which confirmed the diagnosis. The child was then ordered hospitalized and under a general anaesthesia a mastoid operation was performed. During the procedure the doctor removed the hemorrhagic granulations and bleeding vessels in the periosteum and deeper layers of skin and tied them with catgut ligatures to prevent further hemorrhage. This catgut with which the blood vessels had been tied off was intentionally permitted to remain in the wound after the skin was sutured over with silk thread.

The patient came out of the operation satisfactorily and the doctor personally attended to dressing the wound for about ten days at the hospital, and then from time to time at his office for about four months further. During all that time the patient progressed extremely well. The wound healed uneventfully with the exception of a furuncle that developed above the scar which was opened and drained after which it rapidly healed. When the doctor terminated his treatment of the patient there was a scab over the scar, and the child was in excellent condition in every way.

Suit was thereafter instituted by the father on behalf of the child. It was claimed that the catgut used did not absorb but kept the wound from healing for many months until the father took the child to another physician who pulled out the piece of catgut which had come to the surface and told the father that this catgut was interfering with the healing process. The plaintiff's pleadings set forth that the child had, because of the negligence and unskillfulness of the defendant, an open, running and festering wound at the point where the operation was performed. Large damages were demanded.

The plaintiff in this case failed to comply with the demand for a bill of particulars, made on behalf of the defendant, as to the charges in the complaint, and failed to bring on the case for trial. A motion to dismiss the suit for lack of prosecution was successful and finally terminated the matter in the doctor's favor.

NEWS NOTES

THE COUNCIL

The Council of the Medical Society of the State of New York met at 2 o'clock on Thursday, December 11, 1930, in the rooms of the Society in the building of the New York Academy of Medicine, at 2 East 103rd Street, New York, with twenty-nine members present. The Council is the legislative body of the State Society when the House of Delegates is not in session, and its membership is made up of 32 members as follows:

The elected officers.

The chairmen of the Standing Committees.

The Presidents of the eight District Branches.

The Editor-in-Chief of the Journal.

The retiring President.

Twenty-nine of the members attended the meeting, and the President, Dr. W. H. Ross, presided.

A communication from the Secretary of the Otsego County Medical Society requested a ruling of the Council regarding the recognition of members of the staff of a hospital which offers to provide medical service to anyone paying a certain sum to the hospital annually. The Council reaffirmed its general position regarding contract practice, and requested the Committee on Public Relations to investigate conditions in Otsego County. (See page 37).

The Council considered a request from a member for information regarding the liability of a physician for supplying an insurance company with information regarding a deceased person in addition to that required in the death certificate.

It was suggested that this was a proper subject for the Counsel of the Society to discuss editorially in the Legal department of the Journal.

Dr. Heyd discussed the "anti-vivisection" bill now before Congress forbidding the use of living dogs for biological experiments. This bill affects every State Society, and was discussed at the A. M. A. conference of State Secretaries and Editors on November 15, (see this Journal, December 1, 1930, page 1434). On motion the Secretary was authorized to draw up a protest against the bill, and forward it to the Committee on Legislation of the American Medical Association, which has charge of the medical opposition to the bill.

Dr. O. S. Wightman, editor-in-chief, reported that the advertising receipts of the Journal were nearly equal to those of last year—the greatest in the history of the Journal—the drop being only two and three-tenths percent, while periodicals generally had lost from twenty to fifty percent of their advertising income because of the business depression.

Dr. W. H. Ross reported on the relation of the Medical Society of the State of New York to the New York State Health Commission, of which he is a member. (See page 39).

The chairman of the Committees of the State Society gave formal reports enumerating their major activities during the year.

Several routine items of business were discussed and actions on them were authorized.

Adjournment at 4.30 P.M.

COMMITTEE ON PUBLIC RELATIONS

1. ABSTRACT OF REPORT TO THE COUNCIL, DECEMBER 11, 1930

The Public Relations Committee is encouraged in its efforts by many very apparent evidences of co-operation in health work which is noted in our county medical societies, and in letters of inquiry received relating to the work of the State Committee and its County Units. It is worthy of note that very few controversial measures have come before your committee for adjustment.

The members of this committee have been actively at work addressing County Societies, District Branch meetings and various medical gatherings with reference to the necessity of vigorously carrying on the work of the County Medical Society Public Relations Committees, thus endeavoring to activate county committees to as great an extent as possible.

Health surveys from eighteen counties in the State have been received and published in the NEW YORK STATE JOURNAL OF MEDICINE.

Bulletins and letters relating to the work to be performed by the County Units have been regularly submitted to the County Society Committees on Public Relations and others interested in the activities of this State Committee. We aim to keep the County Society Committees informed of the activities of the State Committee and of what is expected of them as County Committees, and have stressed the point that our County Society Public Relations Committee must

be made up of leaders in the medical profession; that they must be aggressive and co-operative, for their success will depend upon the ability of the members to impress the public with the viewpoint of organized medicine and secure active co-operation of other Public Health agencies.

A conference of the chairmen of the Public Relations Committees of the County Medical Societies of this State was held in Albany, September 18, 1930. (See this Journal, October 1, 1930, page 1179.)

The discussion, participated in by twenty-two of the thirty-two members present, was intensive and inspiring, demonstrating that in many of the counties real progress is being made far in advance of what we could have anticipated for the limited period of time that these committees have existed. Furthermore, this conference demonstrated that the personnel of the County Committees had been well selected, as the chairmen present were in most instances the leaders in their respective county societies, men who recognize that there is an issue at stake and will seek out its solution. To those of us who have been hoping to see definite leadership by our County Public Relations Committees, it was most encouraging to note the personnel and intensity of those present.

Your committee has given much time, thought and consideration to the rules and regulations to govern the developing county hospitals that are to receive State aid. These hospitals are general hospitals and the one at Warsaw in Wyoming County is in active operation. The second one in Lewis County is in the course of construction.

The following rules and regulations were recommended by your committee and received the sanction of the executive committee:

"All duly registered physicians of the county may be members of the medical staff.

"From their number they shall nominate for election by the Board of Managers a medical board of five members.

"The medical board shall make recommendations to the Board of Managers for appointments for the necessary, efficient and adequate surgical, medical and special services of the hospital; shall amplify the rules and regulations for the conduct of the professional work of the hospital; and shall formulate whatever By-Laws seem necessary for the efficient conduct of its (Medical Board's) business. Before such rules, regulations and by-laws shall become operative, they must be approved by the Board of Managers."

As indicated by this resolution, the committee was unanimous in feeling that every provision should be made to guarantee the privileges of these county hospitals to every practicing physician in the county.

A study of the Health Services in colleges and universities of New York State by one member of our committee, Dr. O. W. H. Mitchell, of Syracuse, has been made and published in the NEW YORK STATE JOURNAL OF MEDICINE of November 1, 1930. This represents a piece of work which will be invaluable in its influence in leading to better education in health matters, and in instilling into the minds of the youth of our State a proper appreciation of health and disease prevention. Reprints of this study have been obtained and will be distributed widely.

2. REPORT OF MONTHLY MEETING

The regular monthly meeting of the Committee on Public Relations of the Medical Society of the State of New York was held on December 15, 1930, in the Society rooms in Albany, with Chairman, Dr. James E. Sadlier, of Poughkeepsie, presiding.

Dr. Sadlier reported on a conference with Dr. Thomas Parran, Jr., State Commissioner of Health, regarding the Commissioner's approval of the rules and regulations for the staffs of county hospitals receiving State aid. Some of the local physicians in the counties felt that the "closed" hospital was necessary to insure the best grade of medical service. However, both the Commissioner and the members of the Committee on Public Relations favored the principle that the hospital should be "open" to every physician practicing in the county, but that standards of service should be adopted and maintained by the voluntary action of the members of the medical staffs. The following recommendations for rules and regulations governing State Aided County Hospitals were approved at the conference:

1. All registered physicians residing in the county shall be eligible to membership on the staff. Physicians residing outside of the county may use the hospital, but cannot become voting members of the staff.
2. From their number they shall nominate for election by the board of managers a medical board of not less than five members.
3. The medical board, subject to the approval of the board of managers and the State Commissioner of Health, shall have supervision and control of all medical service in the hospital. This shall include appointments for the necessary, efficient and adequate surgical, medical, special and nursing services of the hospital; the preparation of rules and regulations for the conduct of the professional work of the hospital; and the formulation of whatever by-laws seem necessary for the efficient conduct of its (medical board's) business.

A sub-committee, consisting of Drs. Fisher and Hambrook, reported on the Welfare and the

Crippled Children's Laws, and recommended that the following procedure be adopted:

The State Departments of Health, of Education, and of Social Welfare, should help in finding the children who are in need of medical service, and should then give the local physicians the opportunity to supply the service, both medical and surgical. The Committee on Public Relations considered a statement of this principle to be necessary because some crippled children had been sent to State hospitals for operation and care, when they could have been treated in their homes or in local hospitals by local physicians. The excuse of lack of funds for local treatment has been answered by the Welfare Law requiring county superintendents to supply medical care to those who otherwise would be unable to obtain it.

The committee also discussed the general medical service offered to the people of the village of Cooperstown by means of paid membership in the Bassett Hospital Guild. This subject had been assigned to the committee on December 10 by the council, for study and observation. A description of the Guild will be found on page 37.

The committee recognized the fact that a new method of giving medical service is offered to the people of an entire village by an endowed hospital of high standing, and its members decided to observe the Guild in operation, and to judge its methods and results after it has had time to justify its existence and the expectations of its promotors. The experiment may have a special value as a contribution to the study of the cost of medical care.

The Committee will meet in conference with the chairmen of the public relations committees of the five counties of Greater New York, January 8, 1931, at 10 A. M., in the State Society Rooms, Academy of Medicine, 2 East 103rd Street, New York, the object being to discuss the problems relating to public relations in the Metropolitan district.

PUBLIC HEALTH AND MEDICAL EDUCATION COMMITTEE

REPORT TO THE COUNCIL, DECEMBER 11, 1930

The Committee's program for graduate education has consisted of eight postgraduate courses and one clinical day arranged for the following counties. (The subject of the courses with the number of lectures in each course are given after each county).

Wayne County (with Ontario) Heart Course..5 lectures
Seneca County Heart Course .....5 lectures
Rockland County Heart Course.....5 lectures
Tioga County Periodic Health Examinations..4 lectures
Cortland County General Medicine.....6 lectures
Washington County Clinical Day.....5 lectures
Monroe County (with Livingston) Tuberculosis .....5 lectures
Genesee County (with Wyoming and Orleans) Tuberculosis .....5 lectures
Sullivan County Traumatic Surgery .....6 lectures

A summary of this work follows: (The figures for the preceding year also appear).

	1930	1929
Total number of courses.....	9	9
Total number of lectures.....	41	49
Number of county medical societies before which courses were given	13	12
Total attendance of all courses.	1,192	1,623
Largest attendance for one course	566(Monroe)	841*
Smallest attendance for one course.	59(Tioga)	57**
Total cost of all courses.....$1,871.31		$1,745.38
Average cost per course.....	207.92	193.93
Average cost per county.....	143.95	145.45
Average cost per attendance....	1.57	1.08

*Monroe County
**Rockland County

Inasmuch as there are still some lectures to be given in the Sullivan County Course, and also because the committee has not received vouchers for the expenses of all the lecturers, some of the figures in the above summary are based on estimates. While Monroe County had the largest attendance, namely 566, this, however, represents only 25 per cent of its membership. However, in Tioga County, which is recorded as having the smallest attendance, 71 per cent of the county's membership attended the lectures. The attendance in Washington County was much lower than the attendance in Tioga County. As this was a clinical day consisting of five lectures it is hard to compare it with the results in the counties where weekly courses were given. The small attendance in Washington County was due to many factors. Several medical meetings were held in that county within short intervals of the time of the clinical day of lectures; the location at which the lectures were given, while most suitable because of the arrangements, was nevertheless a poor one from the standpoint of convenience and accessibility to the county membership; and some criticism might be made of the effort made to acquaint the members regarding the lectures. Despite these conditions it would seem that the experience with the clinical day of several lectures was not satisfactory, and that the plan of weekly single lectures is undoubtedly more satisfactory.

All of the county societies which had graduate courses this fall with the exception of Cortland and Seneca Counties had had courses in the fall

of 1929. A comparison of their attendance is herewith given:

	Percentage of Attendance 1929	1930	
Wayne County	36%	35%	
Rockland County	30%	39%	
Tioga County	78%	71%	
Monroe County	38%	25%	
Genesee County	43%	51%	
Sullivan County	75%	51%	this is an average
Washington County	35%	27%	

A graduate course was given in Seneca County this fall for the first time since this work has been completely under the direction of the State Society. The attendance at this course consisted of 75 per cent of the membership and the course was very well received.

Outlines for new courses have been furnished by Dr. Luther Warren of Brooklyn and Dr. Burton Simpson of Buffalo on the subject of Internal Medicine and Cancer, respectively.

Arrangements have been made for a course to be given during the spring in Chemung and Steuben Counties. These two counties for the first time will enter into a joint arrangement whereby the same course will be given in Steuben County during the afternoon and will be repeated in Chemung County in the evening. Tentative arrangements with several other counties are pending.

Other activities in which the committee is interested are: a study of the Health Survey made in Steuben County by Dr. Allen Freeman, preparation of articles for publication on Preventive Medicine and work in Cancer Prevention. The work in Cancer Prevention is under the direction of a special committee which is a sub-committee of the Committee on Public Health and Medical Education. This committee held its first meeting on October 10th in the State Society rooms in New York City. Its activities will be directly concerned with the educational aspect of cancer among the medical profession.

Since the last meeting of the committee the chairman has attended all the meetings of the Executive Committee, several of the district branches, conferences of the various officers of the State society, and the meetings of the various committees. On November 13th he was the guest of the Chemung County Medical Society at which meeting he discussed the subject of graduate medical education.

Respectfully submitted,

THOMAS P. FARMER, *Chairman.*

December 11, 1930.

THE BASSETT HOSPITAL GUILD OF COOPERSTOWN

A unique plan of supplying medical service to the people of a large village has been evolved by the managers of the Mary Imogene Bassett Hospital in Cooperstown, Otsego County, New York. The village has a population of 2,725. The medical directory of 1930 lists eleven physicians practicing in the village, eight of whom are on the staff of the Bassett Hospital under pay for full time service.

The managers of the hospital have been planning for some months to establish a system by which the members of the hospital staff will supply the people with medical service along all lines, except obstetrics and chronic diseases, at a fixed price per year. Solicitors have made a canvass of the inhabitants and have distributed copies of a four-page pamphlet entitled "The Purposes and Regulations of the Bassett Hospital Guild." An unlimited amount of medical service of the hospital will be given to those who subscribe to the Guild at $25.00 annually for an individual, or $100.00 for a family of any size. The details of the service to be given by the Guild are set forth in the pamphlet, as follows:

THE BASSETT HOSPITAL GUILD, COOPERSTOWN, NEW YORK

1. *What is the purpose of the Guild?*
   The purpose of the Guild is to reduce the cost of sickness for those needing medical or surgical care. It aims to divide up the cost of sickness among the sick and the well, so that a prolonged illness or a surgical operation will not be a financial calamity for people of moderate means.
2. *Who may join the Guild?*
   Any individual residing in or near Cooperstown who is not suffering from some chronic illness at the time the application for membership in the Guild is made. Whenever it seems advisable, a physical examination by a member of the Hospital Staff will be required.
3. *Is membership in the Guild open to individuals residing outside of the village limits of Cooperstown?*
   Yes, any individual not chronically ill at the time application for membership is made, and living in or near Cooperstown, is eligible. Those whose place of residence is not easily accessible will not be entitled to receive free of charge any house calls from members of the Hospital Staff.
4. *How much does it cost to join the Guild?*
   $25 a year for each individual.
   $100 a year for an entire family of any size.
   The dues may be paid in monthly instalments if the member so desires.
5. *What period of time is covered by such a membership?*
   From January 1, 1931, to January 1, 1932.
   Memberships will become effective one month after an application has been accepted.
6. *What privileges are accorded members of the Guild?*
   The Mary Imogene Bassett Hospital, through its Staff, will take care of Guild members in case of

any illness, either medical or surgical, without additional charge. Depending upon the severity and the kind of illness, the doctors of the Hospital Staff will care for the patients at home, in the doctors' offices at the Hospital, or as ward patients in the Hospital.

7. *Are accident cases, surgical operations and, when necessary, ambulance service, included in Guild service to members?*
   Yes.

8. *Is there any type of medical or surgical service not rendered to Guild members?*
   Care of obstetrical cases is not included in this service.

9. *What is to be done about cases coming under the Workmen's Compensation Act?*
   Such cases are to be handled as heretofore.

10. *If a member of the Guild carrying an accident policy in an Insurance Company, or entitled to money from an Insurance Company because of injury by another person who is insured, is the Hospital entitled to any of the money paid by the Insurance Company?*
    Yes, the Hospital would expect to receive the amount covering the usual charge for the care given by the Hospital Staff.

11. *What services are included under Hospital ward care?*
    X-rays, laboratory examinations, professional services, operations when necessary, and all routine nursing care.

12. *Is it possible for Guild members to have Private Room service if admitted to the Hospital?*
    If a member upon admission to the Hospital desires private room service, he will be allowed a credit of $4 a day. With this deduction, the charge for private room service, operation, laboratory work, professional fee, etc., will be computed as for non-members.

13. *Can Guild members have their choice of doctors on the Hospital Staff?*
    In so far as it is practicable, it will be the aim of the Hospital to comply with the wishes of patients in their choice of doctors.

14. *If a Guild member is admitted to the Hospital, is there any limit to the length of time which he can continue to receive Hospital ward service without additional cost to him?*
    There will be no additional charge during the term of membership if the illness is of long duration.

15. *Who shall decide where a member shall be treated?*
    The doctors of the Hospital Staff reserve the privilege of deciding whether an illness is to be treated at home, in the office, or by admission to the Hospital.

16. *Is it possible for one individual to take out memberships for other individuals or families?*
    Yes, any person may subscribe for as many memberships as he desires. An individual or family may subscribe for another family, or an employer may, if he wishes, take out memberships for each of his employees.

The dues of the members of the Guild will be paid to the hospital; and the physicians will serve for fixed salaries to be paid by the hospital. The service gives rise to important questions in medical ethics, such as the standing of the members of the staff as "contract" doctors, and legal points connected with the practice of medicine by a corporation. The members of the Committee on Public Relations of the Medical Society of the State of New York to whom the entire service of the Guild was referred for investigation and observation, have taken a broad view of the situation, and will withhold judgment for the present (See page 36).

The Guild pamphlet closes with the following note of information:

"The Bassett Hospital Guild is offered to the community as something of an experiment. The success of the plan depends largely upon the number of its subscribers, and upon a spirit of cooperation between the Guild members and the members of the hospital staff. It is hoped that a sufficient number of members can be enrolled within the next six weeks to make it possible to put the plan in operation on January 1, 1931. If, after a trial for one year, the Guild is satisfactory, both from the point of view of the hospital and of the members of the Guild, it is the intention of the hospital to make it a permanent organization."

COMMITTEE ON PERIODIC HEALTH EXAMINATIONS

The special Committee on Periodic Health Examinations met at the Academy of Medicine in New York City, on December 20th, for the purpose of considering the program for work during the coming year. The following were present:

Dr. C. Ward Crampton, Chairman
Dr. W. Warren Britt
Dr. Walter A. Calihan
Dr. Nellis B. Foster
Dr. Walter D. Ludlum
Dr. Marion Craig Potter
Dr. Guy H. Turrell.

The following members of the Executive Committee of the Council were also present:

Dr. William H. Ross
Dr. John A. Card
Dr. James N. Vander Veer
Dr. W. Ross Thomson.
Dr. Thomas P. Farmer.

The Chairman reported that the banquet meeting of the Periodic Health Committee held in Rochester June 4, 1930, after the close of the Annual meeting, had been attended by Mrs. R. R. Vail, Executive of the State Parent-Teachers Association, and Miss Harriet Mayer, of the

New York State General Federation of Women's Clubs (see this Journal, June 15, page 737), and that these two organizations had passed resolutions favoring periodic health examinations.

The resolution of the Parent-Teachers Association on October 9th, was as follows:

"Whereas, The Summer Round-up has demonstrated the advantages of the physical examinations of the pre-school child and

"Whereas, The physical examination of an adult is of equal importance,

"Therefore be it Resolved, That every District of the New York State Congress of Parents and Teachers shall, through its Health Chairman, provide its members with accurate and up-to-date information as to the value of an annual health examination, and encourage its members to have such examination"

The resolution passed by the Federation of Women's Clubs in November, was as follows:—

"Whereas, examinations for the discovery of defects in 'Well Baby Clinics,' 'Summer Round-ups' of pre-school children and children in the public schools have demonstrated this practice to be effective for the health of the child and one bearing directly upon its future welfare and

"Whereas, in our program for the prevention of disease and the prolongation of life, a check-up for adults is of corresponding importance; therefore

"The Division of Health of New York State Federation of Women's Clubs recommends that each club seek to promulgate the education among its members of the value of a health examination by a competent physician and record the number examined; and The Division of Health urges that the Federation in convention assembled endorse this recommendation."

The Committee intends to submit to the Journal, for publication, material calculated to be of aid to the physicians who may be called upon to give health examinations to members of these organizations.

After so doing, they will feel at liberty to advise these organizations that the physicians have been informed and are ready.

The Committee, through its Chairman, has asked the publication Committee to print this information in the Journal and to invite suggestion and comment thereon from members of the Society.

The chairman described a "Health Exhibit" conducted in the Women's Building at the Rochester Exhibition during the first week of September, 1930. The exhibition is a non-profit organization promoted by the leading citizens of the community for the benefit of Western New York. It is comparable in many features to the State Fair at Syracuse. It has been held annually the week of Labor Day for the past twenty years. This year, there was a reported attendance of nearly two hundred thousand. The Women's Building was built for civic and educational enterprises and the display of exhibits. It is the only building exempt from payment for space.

The Health Exhibit was sponsored by the Health Committee of the Federation of Women's Clubs, and was visited by more than 18,000 persons. A large number of organizations contributed to the exhibit including the Committee on Periodic Health Examinations, the Tuberculosis and Health Association of Rochester, Monroe County, and the Rochester Gas and Electric Corporation.

Moving pictures were shown continuously and a great amount of health literature was distributed.

The Exhibit aroused a widespread interest in health matters, and especially in personal health, of which the periodic health examination is the concrete expression.

C. WARD CRAMPTON, *Chairman.*

NEW YORK STATE HEALTH COMMISSION

This Journal of May 15, 1930, carried an account of the appointment of the New York State Health Commission of fourteen members by Governor Franklin D. Roosevelt, for the purpose of:

"1. The consideration of public health activities of State and local authorities, and their relation to one another.

"2. Recent progress in public health in other states and abroad.

"3. To submit any conclusions and recommendations which it may deem wise relating to either the legislative or administrative aspects of public health."

Dr. Livingston Farrand, President of Cornell University, was made Chairman of the Commission. Dr. Farrand is a doctor of medicine who has the point of view of the practising physicians, and has had a wide experience in public health administration.

The Secretary of the Commission is Dr. Thomas Parran, Jr., Commissioner of Health of New York State.

The Commission assigned each of its members to the chairmanship of a sub-committee on a particular subject; and each chairman was authorized to appoint associate members. The subcommittees chosen were as follows:

Cancer: Chairman, Dr. George W Cottis, Jamestown surgeon.

Associates: Dr. R. V. Brokaw, American Society for

the Control of Cancer, 25 West 43rd Street, New York City.

Dr. James Ewing, Cornell Laboratory, 477 First Avenue, New York City.

Dr. Burton T. Simpson (Secretary), Director, New York State Institute for the Study of Malignant Disease, 115 High Street, Buffalo, N. Y.

Dr. Francis Carter Wood, 1145 Amsterdam Avenue, New York City.

Dr. Howard Taylor, 20 West 53rd Street, New York City.

Laboratories: Chairman, Dr. Simon Flexner, Rockefeller Institute for Medical Research, New York City.

Associates: Dr. Stanhope Bayne-Jones, 62 Dartmouth Street, Rochester, N. Y.

Dr. Thomas Ordway, Dean Albany Medical College, Albany, N. Y.

Dr. William H. Park, N. Y. C. Bureau of Laboratories, Foot of East 16th Street, New York City.

Colonel F. F. Russell, Rockefeller Foundation, 61 Broadway, New York City.

Dr. A. B. Wadsworth, (Secretary), Director, Division of Laboratories, Albany, N. Y.

Local Health Service: Chairman, Dr. Thomas J. Parran, Jr., New York State Commissioner of Health, Albany, N. Y.

Associates: Mr. W. P. Capes, Executive Secretary, Conference of Mayors, City Hall, Albany, N. Y.

Dr. W. P. Draper, Asst. Surgeon General, U. S. Public Health Service, Washington, D. C.

Dr. John A. Ferrell, Rockefeller Foundation, 61 Broadway, New York City.

Dr. Allen W. Freeman, Johns Hopkins School of Hygiene and Public Health, 615 North Wolfe Street, Baltimore, Md.

Medical Care: Chairman, Dr. W. H. Ross, Brentwood, President of the Medical Society of the State of New York.

Associates: Dr. A. T. Davis, County Health Commissioner, Suffolk County, Riverhead, N. Y.

Dr. Joseph S. Lawrence, Executive Officer, State Medical Society, 100 State Street, Albany, N. Y.

Dr. W. S. Rankin, The Duke Endowment, Power Building, Charlotte, N. C.

Mr. Barry C. Smith, The Commonwealth Fund, Fuller Building, 57th Street and Madison Avenue, New York City.

Dr. Nathan B. Van Etten, 300 East Tremont Avenue, New York City.

Mental Hygiene: Chairman, Mr. Homer Folks, Secretary, State Charities Aid Association, New York City.

Associates: Dr. John E. Burke, School Medical Director, 1308 State Street, Schenectady, N. Y.

Dr. Eric Kent Clarke, Assistant Professor of Medicine, School of Medicine and Dentistry, University of Rochester, Rochester, N. Y.

Dr. Elizabeth M. Gardiner, Director, Division of Maternity, Infancy and Child Hygiene, State Department of Health, Albany, N. Y.

Dr. Richard H. Hutchings, Superintendent Utica State Hospital, Utica, N. Y.

Mr. Charles H. Johnson, Director, State Department of Social Welfare, Albany, N. Y.

Dr. Harry L. Levin, Clinical Director, Buffalo State Hospital, Buffalo, N. Y.

Dr. Cayce Morrison, Assistant Commissioner for Elementary Education, State Department of Education, Albany, N. Y.

Dr. Frederick W. Parsons, Commissioner State Department of Mental Hygiene, Albany, N. Y.

Dr. George S. Stevenson, Field Work Consultant, National Committee for Mental Hygiene, 370 Seventh Avenue, New York City.

Mr. Arthur Towns, Secretary, Onondaga Health Association, 327 Montgomery Street, Syracuse, N. Y.

Dr. Theron J. Vosburgh, Gracelands Hospital, Westchester County, Valhalla, N. Y.

Orthopedics: Chairman, Mr. Henry Morgenthau, New York City.

Associates: Mr. Frederick Brown, 565 Fifth Avenue, New York City.

Miss Sarah Schuyler Butler, 9 East 41st Street, New York City.

Dr. Walter S. Craig, Director of Division of Orthopedics, State Department of Health, Albany, N. Y.

Miss H. Ida Curry, State Charities Aid Association, 105 East 22nd Street, New York City.

Mr. Charles Johnson, Department of Social Welfare, Albany, N. Y.

Mrs. Sarah Kirkendall, 119 Albany Street, Ithaca, N. Y.

Mr. Raymond Knoeple, 5 Beekman Street, New York City.

Dr. Louis Wilson (Secretary), State Department of Education, Albany, N. Y.

Miss Lillian D. Wald, 265 Henry Street, New York City.

Public Health Law: Chairman, Dr. Matthias Nicoll, Jr., White Plains, Commissioner of Health Westchester County, and lately Commissioner of Health of New York State.

Associate: Dr. Edward H. Marsh, State Department of Health, Albany, N. Y.

Public Health Education: Chairman, Mrs. Henry Goodard Leach.

Associates: Mr. Bertrand Brown, Milbank Memorial Fund, 49 Wall Street, New York City.

Mr. Edward F. Brown, Director, Diphtheria Prevention Commission, New York City Department of Health, 505 Pearl Street, New York City.

Public Health Nursing: Chairman, Miss Katherine Tucker, Director National Organization for Public Health Nursing, New York City.

Associates: Miss Mary Thornton Davis, Director, Public Health Nursing Association, Inc., 130 Spring Street, Rochester, N. Y.

Miss Elizabeth Fox, Superintendent New Haven Visiting Nurse Association, New Haven, Conn.

Miss Amelia Grant, Director, Bureau of Nursing, Department of Health, 505 Pearl Street, New York City.

Miss Mathilde S. Kuhlman (Secretary) Director, Division of Public Health Nursing, State Department of Health, Albany, N. Y.

Sanitation: Chairman, Dr. Matthias Nicoll, Jr., White Plains, Commissioner of Health Westchester County, and lately Commissioner of Health of New York State.

Associates: Mr. George W. Fuller, c/o Fuller and McClintock, 170 Broadway, New York City.

Mr. Charles A. Holmquist (Secretary), Director, Division of Sanitation, State Department of Health, Albany, N. Y.

Professor Henry N. Ogden, Cornell University, Ithaca, N. Y.

Child Health: Chairman, Dr. Livingston Farrand, President Cornell University, Ithaca, N. Y.

Associate: Dr. Elizabeth M. Gardiner, Director, Division of Maternity, Infancy and Child Hygiene, State Department of Health, Albany, N. Y.

Social Hygiene: Chairman, Dr. Edward L. Keyes, President American Social Hygiene Association, New York City.

Associates: Dr. Walter Brunet, New York Tuberculosis and Health Association, 244 Madison Avenue, New York City.

Dr. Albert Pfeiffer (Secretary), Director, Division of Social Hygiene, State Department of Health, Albany, N. Y.

Dr. William F. Snow, Director, American Social Hygiene, Association, 370 Seventh Avenue, New York City

Tuberculosis: Chairman, Mr. John A. Kingsbury, Milbank Memorial Fund, New York City.

Associates: Dr. Reginald M. Atwater, County Health Commissioner, 302 Laurens Street, Olean, N. Y.

Mr. Baily B. Burritt, General Director Association for

Improving the Condition of the Poor, 105 East 22nd Street, New York City.

Miss Alta E. Dines, Director of Nursing Service, Bureau of Educational Nursing, Association for Improving the Condition of the Poor, 105 East 22nd Street, New York City.

Dr. Albert H. Garvin, Director, Buffalo Tuberculosis and Health Association, 370 Seventh Avenue, New York City.

Dr. Henry E. Kleinschmidt, Medical Secretary, National Tuberculosis Association, 365 Military Road, Buffalo, N. Y.

Mr. George J. Nelbach, State Charities Aid Association, 105 East 22nd Street, New York City.

Dr. Robert E. Plunkett, (Secretary), Director, Division of Tuberculosis, State Department of Health, Albany, N. Y.

Dr. Frederick Rand Rogers, Director, Bureau of Welfare, Physical Education and Health Teaching, State Department of Education, Albany, N. Y.

Mr. Fred M. Stein, New York City Tuberculosis Association, 244 Madison Avenue, New York City.

Dr. Nathan B. Van Etten, 300 East Tremont Avenue, Bronx, New York City.

Dr. E. R. Baldwin, Trudeau Foundation, Saranac Lake, N. Y.

Dr. Lawrason Brown, Trudeau Sanatorium, Saranac Lake, N. Y.

Dr. E. P. Kolb, Suffolk County Sanatorium, Holtsville, N. Y.

Dr. George C. Ruhland, Department of Health, Syracuse, N. Y.

Miss Grace L. Anderson, East Harlem Nursing & Health Service, 354 East 116th Street, New York City.

Mr. Harry L. Hopkins, Director, New York Tuberculosis and Health Association, 244 Madison Avenue, New York City.

Mr. Edward Hochhauser, Committee for the Care of the Jewish Tuberculous, 67 West 47th Street, New York City.

Public Health Personnel: Chairman, Dr. Linsly Williams Director New York Academy of Medicine.

Associates: Dr. Livingston Farrand, Office of the President, Cornell University, Ithaca, N. Y.

Dr. Thomas Parran, Jr., Commissioner of Health, Albany, N. Y.

Dr. Matthias Nicoll, Health Commissioner, 158 Martine Avenue, White Plains, N. Y.

Hon. Homer Folks, State Charities Aid Association, 105 East 22nd Street, New York City.

Mr. John A. Kingsbury, Milbank Memorial Fund, 49 Wall Street, New York City.

Surgeon General Hugh S. Cumming, U. S. Public Health Service, Washington, D. C.

Dr. Haven Emerson, 630 West 168th Street, New York City.

Dr. Allen W. Freeman, Johns Hopkins University, Baltimore, Md.

Dr. Edward S. Godfrey, State Health Department, Albany, N. Y.

The Commission and its sub-committees are composed of ninety-two members, representing nearly every phase of civic medicine and public health, and their opinions will carry the weight which belongs to experts in their several lines.

JEFFERSON COUNTY

The December meeting of the Jefferson County Medical Society was held on December 11th, at the Black River Valley Club. Dinner was served at 6:30, and the meeting was called to order at 7:45, President Walsh presiding.

A report from the Public Relations Committee was made by Chairman Olin. About twenty-five meetings have been addressed around the County in the interest of the County Health Unit. He read a letter from Dr Ross, President of the State Society, emphasizing the point that, in Suffolk County, the county health administration has, in these two years of operation, had no interference from the State Department. It pursues its own policies and has all freedom in the choice of a health officer. All that Albany seems to want is the assurance that local work is progressing satisfactorily. Two letters from Dr. Parran, Commissioner, bore out the same statements relative to non-interference from the State Department.

The proposition is now ready for presentation to the Board of Supervisors. After considerable thought, and some difficulties, the committee was now of the opinion that the best way to do this would be for the communication to be put in writing and read to the Board by the Secretary of the Medical Society, the health officers from the rural sections being especially urged to be present. Advice was asked, but no other suggestions were offered.

A report of the Legislative Committee was made by Dr. Calkins. Due to lack of time, the Committee had not been able to act on the proposed agreement with Compensation Carriers, as authorized at the last meeting. The proposed agreement was read, and minor points, possibly objectionable, were pointed out. After discussion, Dr. Calkins moved that the agreement be accepted without reservation, and the cause of our delayed action explained; seconded by Dr. Gardner, and carried.

A motion was then made that the President appoint a committee of three to draw up a fee-schedule, as required by the above agreement. Seconded and carried. Dr. Gardner requested that the Secretary obtain a copy of the fee-schedule of one of the counties in the Metropolitan area.

Dr. Walter Atkinson moved that the Secretary be authorized to send flowers to Dr. Hawkins, Mrs. Hawkins having just passed away, also that a committee be appointed to draw up resolutions. Seconded and carried.

Dr. Metzger then gave his address, as retiring President. He dealt with the "demerits" of the County Health Unit plan. He thought the health authorities of a village would know more about the village health problems than a county health officer; that politics might play an undesirable part in the appointment of the county board and the health officer; and that there might

be undue interference in policies and program from outside sources. He quoted freely from an address given by Dr. Morris, Secretary of the Cattaraugus County Society. It was not so much an attack on the county unit idea as it was a friendly effort to point out minor defects.

Five members were scheduled to speak on "Observations at the Last Meeting of the American College of Surgeons."

Dr. Walter Atkinson asked to be excused because so few are interested in eye work.

Dr. Cooper spoke interestingly of a new theory about forcing fluids. In some diseases, e.g., toxemia of pregnancy, it is possibly better to limit them.

Dr. Thornhill sounded a warning about "Thymophysin," the new drug advertised as a "reliable and safe means of accelerating delivery," with opinions from Philadelphia and the A. M. A. He spoke of various forms of local anesthesia coming into favor, of the talking pictures exhibited, and lastly of the willingness of prominent surgeons to confess inability to make a diagnosis, provided the case had been carefully studied.

There were forty members present, and two guests.

Adjournment at 10 P. M.

W. S. ATKINSON, *Secretary.*

TIOGA COUNTY

A general hospital for Tioga County was dedicated on the afternoon of Tuesday, November 25, with elaborate ceremonies. The hospital was built at a cost of over $200,000, raised by subscriptions, and is therefore not under the control of the governmental officials of the county, as are the hospitals of the counties of Lewis and Wyoming; and it is the center for the entire medical profession of Tioga County represented by the County Medical Society.

The hospital will be more than a place where sick persons are treated; it will be an educational center, at which scientific standards of diagnosis and treatment will be maintained. While it will be open to all physicians in the county, yet they have voluntarily adopted high standards of practice and will maintain them by monthly staff conferences. The importance of the hospital as a center of graduate education is indicated by the fact that the list of speakers included a group of officers of the Medical Society of the State of New York—Dr. W. H. Ross, President, Dr. J. A. Card, Speaker of the House of Delegates, Dr. J. E. Sadlier, Chairman of the Committee on Public Relations, and Dr. J. S. Lawrence, Executive Officer.

The hospital has a capacity of sixty patients and was half filled on the day it was opened.

The Waverly Sun of November 27, 1930, devoted over a page to a description of the hospital and the ceremonies of dedication.

ORANGE COUNTY

The annual meeting of the Medical Society of the County of Orange was held at Mitchell Inn, Middletown, on Tuesday, December 9, 1930, at 6 P. M.

A turkey supper was served to 67 members, this number being the largest at a Society meeting for many years. President S. L. Truex presided at the supper and at the close opened the meeting for nomination and election of officers which resulted as follows:

President.....Earl C. Waterbury, Newburgh
Vice-President.....S. W. Mills, Middletown
Secretary-Treasurer..H. J. Shelley, Middletown
Censors:—M. A. Stevens, H. F. Pohlmon, E. G. Cuddeback, W. H. Snyder.

Delegates to State Society for 1931-1932:—J. B. Hulett; alternate, J. D. Mors.

Delegate, First District Branch:—S. L. Truex; alternate, G. Otto Pope.

The subject of the Relation of Industrial Insurance carriers to the medical profession was presented by Dr. Edgar A. Vander Veer, member of the Committee on Economics, who outlined the principles formulated at a conference of representatives of the County Medical Societies of Greater New York, and the Insurance Carriers which was described in the Journal of November 15, 1930, page 1480. This subject was referred to a special committee to report at a special meeting of the Society on January 12, 1930.

The subject of County Pre-school Clinics was presented through a letter from Dr. Thomas Parran, Jr., State Commissioner of Health. Dr. J. S. Lawrence, executive officer of the State Society, explained the point of view of the State Society. The subject was referred to a special committee to report on January twelfth.

Following a reading of a letter from Dr. Robert Corder complaining of fines imposed for failing to pay the annual registration fee, the following resolution was offered and carried, viz:—

"That the annual registration of doctors be removed and that the Secretary send a copy of

this resolution to the President of the State Medical Society and to the State Department of Education."

The Treasurer's report showed 107 paid-up members.

Dr. John Howell, Chairman of the 125th Anniversary Committee, reported progress and fixed a tentative date in July, 1931, for the celebration.

The Society went on record against fishing, bathing or boating in municipal water supplies of the county.

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on November 19, 1930, was called to order at 9 P.M., with the President, Dr. Gettinger, in the chair.

The following candidates were elected to membership: Drs. Isadore Aronowitz, Thomas I. Brennan, Milton J. H. Grand, Julius Katz, Pincus Marlowe and Joseph W. Wilner.

Dr. Magid submitted the report of the Committee on Medical Economics with special reference to the compensation agreement between the county societies and the insurance carriers. The President stated that, while it is not a perfect plan, thanks are due to the various committees, including the State Committee on Medical Economics, of which Dr. Chandler is chairman, for having brought about this agreement The agreement was further discussed by the members and Dr. Rosenthal, chairman of the Committee on Economics of the Medical Society of the County of New York. Following the discussion, it was moved and carried that the compensation agreement be accepted by the Bronx County Medical Society.

Dr. Bick presented a tentative Report of the Social Committee. A Beefsteak Dinner with a novel entertainment will be held at Ebling's Casino on Wednesday evening, January 28, 1931, only physicians to be admitted. Any profit from this affair is to be credited to the relief fund.

Dr. L. A. Friedman submitted the report of a joint meeting of the committees on Health Examination, and Public Health and Medical Education. The committees recommended that the Bronx County Medical Society go on record as favoring the compulsory immunization against diphtheria before a child is admitted to school.

The Scientific Program then proceeded as follows:

Papers:

1. Modern Cancer Research, Francis Carter Wood
2. Radiotherapy in Cancer, Maurice Lenz
3. Modern Cancer Surgery, George Henry Semken.

I. J. LANDSMAN, *Secretary.*

DELAWARE COUNTY SURVEY

Dr. John E. Safford, of Stamford, Chairman of the Public Health Committee of the Delaware County Medical Society, wrote to Dr Sadlier, on November 27:

"We had no Committee on Public Relations up to two weeks ago, when one was created and Dr. Gordon Maurer of Margaretville was made its Chairman.

"The new Public Relations Committee will make a more complete survey and, no doubt, will cooperate with your State Committee heartily.

"We have been handicapped in our Public Health work by not having a county nurse. In the absence of a nurse, the Secretary of the County Antituberculosis and Public Health, the Home Bureau, the State Department District Nurse, and local lay committees have assisted.

"Since 1924 we have administered toxin antitoxin to 4073 children, 699 of whom were under five years of age; and 1,971 children of pre-school age have been examined, mostly by our own physicians. Our relations with these county lay organizations have always been cordial, and we have led the procession."

THE DAILY PRESS

LESSONS IN RELAXING

The Daily Press Department of this Journal for December 15, 1930, page 1497, contained a description of a course in relaxation in Barnard College, New York City. Numerous comments on the course show that it is to be taken seriously. Tension, both nervous and muscular, is the serious threat to health to children as well as adults, and physicians will welcome a method for overcoming it. An editorial in the New York *Times* of December 11 suggests the following plan which works well in a kindergarten class:

"Barnard College, with its new courses in resting, is but following in the footsteps of a kindergarten in Seattle, Wash. There Miss Winifred Chamberlain has been teaching children the art of relaxation, just as they are taught writing or baseball or dancing.

"Realizing that the average child leads an 'overstimulated life,' she began using the ten-minute rest periods to teach the youngsters how to relax. Mothers provided each child with a clean but rather Spartan resting mat, made of several thicknesses of newspaper covered with wrapping paper. When not in use these are folded so that the clean side never touches the floor.

"The children were shown how to lie down on their mats in a posture found by experiment to induce the greatest relaxation, so that "the child is lying face downward with head turned to left side, the right leg out straight and the left leg slightly bent, throwing most of the weight on the right side." With a little instruction, all took to it like ducks to water.

"Seattle mothers must be grateful to have their youngsters taught how to rest, and in a way which makes it seem a pleasant game. One can easily imagine a precocious and high-strung Junior being invited to perform for visitors by going into his rest instead of speaking a piece; or, better yet, being assigned as "home-work" two hours on the resting mat.

"In the kindergarten the best relaxer was recognized by having his picture displayed in a poster frame labeled "John is showing us the best way to rest." Here at last is a chance for the dullards to come out ahead of the bright youngsters."

CHEESE NAMES

How many kinds of cheese can you name? You would start off with American, Roquefort, Camembert, and Edam, and would probably stop at Limberger. But Beverly Smith, writing in the "Lantern" column of the New York *Herald Tribune* of December 11, says:

"Glancing over the literature of cheeses I find a tentative list of almost 500, ranging from Abertam, a hard rennet cheese made in the mountains of Bohemia, to Zips, a variety of the Brinsen or Brinza which is cunningly concocted of sheep's milk in the Hungarian Carpathians.

"To mention a few at random, there is the Brug-Panir of Armenia, the Bra of the Italian Piedmont, the "Brickbat" of Wiltshire, the Broccio of Corsica, the Caerphilly of Wales, the Chaschol de Chaschosis of Switzerland, the Chhana of Asia, the Damen of Vienna, the Dotter of Nuremberg, the Dunlop of Scotland, the Elbing of West Prussia, the Eriwani of the Caucasus, the Ftinoporino of Macedonia, the Geheimrath of Holland, the Gisley of Denmark, the Goya of the Argentine (Firpo?), the Ilha of Portugal, the Jack of Monterey County, California; the Josephine of Silesia, the Kajmak of Turkey, the Karut of Afghanistan, the Lapland cheese made of reindeer milk and the Neapolitan cheese made of buffalo milk.

"Most of these cheeses, even with the help of our finest bacteriologists and cheesemakers, could not be reproduced in America. The water used, the climate, the provender fed to the cattle—these delicate factors make a good cheese as hard to imitate as Pilsener beer. Even the great chemists of Germany, as you know, have at last abandoned the attempt to produce real Pilsener anywhere except in the little Bohemian town of Pilzen.

"America is beginning, however, to produce rare cheeses of her own. The great army of Americans who travel abroad every summer have learned something of what good cheese can be. They are demanding Camembert and Gorgonzola and Port de Salut at the delicatessen stores."

GIANTS

The frequent references to a race of giants in the older books of the Bible, as Genesis 6:4, have often been taken as scientific truths which have been confirmed by reports of actual skeletons of persons of unusual stature. The New York *Herald Tribune* of December 15 discusses the myths of giants, and compares their persistence and perennial births with those regarding children nurtured by wolves and wheat grown from kernels found in the mummies of the Pharaohs. The editorial says:

"A casual and incomplete census of outbreaks of these three myths of giants, wolf-boys and ancient seeds in the last few years indicates what doctors would call an incidence of about once every six weeks. The curious thing is that any one of these three stories might be true A race of gland-diseased human beings most of whom were giants is not unthinkable. There is no definite evidence that a lost baby might not grow up among animals. No seed ever has been known to live, it is true, as long as thirty centuries, or even as long as two, but no one can call the feat impossible. The only thing against the three stories is that they always turn out false. The giants, for example, probably are ordinary men and women whose bones have been laid out carelessly and measured a foot or two too long. In life there is a long overlap between the human leg bones and the spine, a result of the normal tilt of the bones of the pelvis. Unless an excavator is a skilled anatomist, he usually forgets this when measuring the length of a skeleton, thus magnifying his measurement by a foot or so and imagining a giant is what is merely a wrongly tilted pelvis and insufficiently overlapped legs."

A NON-POISONOUS DENATURANT FOR ALCOHOL

The newspapers have been carrying protests against the use of the poisonous wood alcohol as a denaturant for ethyl alcohol used in manufacturing, on the ground that it gives no manifest sign of its presence when the alcohol is used as a drink. The New York *Herald Tribune*, as well as other newspapers, of December 11, announce the discovery of a safe denaturant after three years of research and experimentation The new substance is described as follows:

The substitute for wood alcohol will be alcotate, a chemical element derived from the production of gasoline through the cracking process The element is supposed to be contained only in petroleum found in California. Industrial alcohol will be treated with 1 per cent alcotate and 1 per cent aldehol, also a petroleum product.

"This rids us of the need of using wood alcohol," said Dr. Doran. "It will not kill or blind and it is more effective for its purpose than wood alcohol. It is a big improvement all around. Alcohol denatured by this process is proof against removal by the most drastic bootleg manipulations. It is harmless if accidentally or purposely taken in quantities to be found in industrial alcohol. It will ruin the taste of beverages prepared from denatured alcohol, however."

RYE BREAD

It is a trait of human beings, both young and old, to acquire a wish to do things forbidden. The New York *Herald Tribune* of December 10 has the following editorial discussion on the compulsory use of rye bread in Germany:

"If we know human nature the Germans are about to acquire a dislike for the strong-tasting, sour rye bread which has been, along with beer, their national pride. For Germany has a surplus of rye and a deficit of wheat, and one of Chancellor Bruening's new economy measures is to forbid the restaurants to sell white bread. Now before the war many a German grew to manhood without even tasting white wheat bread; and when he did taste it, it seemed to him as insipid as water.

"Our ancestors who migrated from England to America may never have tasted white bread; white bread was the exception, something of a luxury, in the England of their day. It was not until the middle of the eighteenth century that wheat became the major constituent of British bread. North France clung longer still to rye; for some curious reason southern Europe never adopted rye at all.

"Russia, of course, still lives on bread which is not only brown but black—a heavy, musty-smelling concoction positively repellent to most Western palates. But taste, in bread as in other matters, is a growth of custom. The Russian peasant does not feel oppressed by being forced to eat black rye bread; he would object more if compelled to subsist on fluffy, crusty, white French rolls. Most of us are arrant reactionaries in matters of food. We like that to which we are accustomed; we fear the strange. Nothing less than a prohibition will force us into new habits."

OUR NEIGHBORS

ANNUAL MEETING IN MICHIGAN

The minutes of the Annual Meeting of the Michigan State Medical Society, held in Benton Harbor, September 15 to 17, 1930, fill pages 821 to 872 of the November issue of the Journal of the Michigan State Medical Society. The report of the Council lists the following activities of the Society:

"1. Publication of the Journal.
"2. Medical Legal Defense.
"3. Joint Committee on Public Health Education.
"4. Post-Graduate Courses in Ann Arbor and Detroit in conjunction with the Post-Graduate Department of the University.
"5. Post-Graduate District Conferences.
"6. Legislative Conferences.
"7. County Society Activities.
"8. Entertainment of Officers and House of Delegates of American Medical Association.
"9. Joint Activity with Standing Committees.
"10. Individual Investigations.

"Our Society has conducted several worthwhile surveys and studies. Notable were those on Tuberculosis, Free Service Hospitals, Need of Additional Accommodations in State Institutions, etc. Valuable contributions have thus been made."

Concerning legislation, the President reported:

"There seems to be among our membership two opinions. The one favoring a passive or non-active attitude and passing the responsibility for maintaining the high standards of practice squarely over the legislature. Aside from the State Department of Health the medical profession has had no assistance in its fight from local boards of health or public officials, and I believe that since the benefits fall upon the public rather than upon us, the job is not entirely ours. Personally I am quite disgusted with the actions of legislators and perhaps if we left them severely alone for a term or two, allowing them to enact all the cult legislation they desired, I am quite convinced that it would react to a public demand for repeal with great benefit to scientific medicine, and a material surcease in our legislative efforts in the future.

"On the other hand there is a group who favor an active legislative campaign—offensive as well as defensive. Among this group are the members of the Wayne County Medical Society Legislative Committee, and the State Legislative Committee. It appears that these two groups differ somewhat as to the method of procedure and the objects in view. Both are meritorious and both will bring results. From my knowledge of them it seems they could work together to mutual advantage."

The following resolution was adopted:

"Whereas, the *Michigan State Medical Journal* in the August, 1930, issue contains the following paragraphs, describing the methods used by the Berrien County Medical Society.

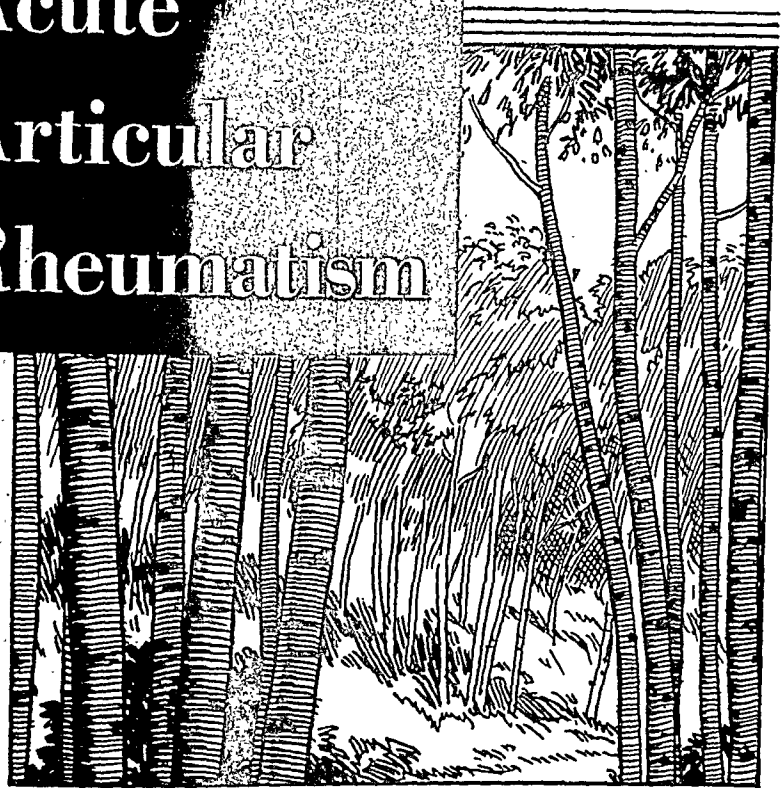
"There are no municipal clinics. Indigent cases come under the care of welfare workers and the public health nurses. Where medical attention is necessary, the patient is allowed to choose his own physicians and the bill for medical services is certified by the social workers and paid by the municipal governments. A reasonable fee is allowed, and there is very little criticism on the part of the public or the medical profession.

"Therefore, be it resolved that we, the House of Delegates, compliment the Berrien County Medical Society as using the best practical methods consistent with all the ethics and traditions of our profession and,

"Further, be it resolved that the various county societies follow their splendid example and apply such methods throughout the State as far as possible during the coming year."

A diagnostic clinic for the Upper Peninsula was discussed:

"Most of you are familiar, I believe, with the donations of Mr. Couzens during the last several years in the interests of child welfare.



"A little over a year ago he made a much larger contribution in the sum of $10,000,000 which is to be expended at the rate of $700,000 a year in the interests of the welfare of the children of Michigan and of the country generally.

"Some months ago, after a survey of the State, it was determined by the Michigan Children's Fund—which is the official name of the organization—to put a clinic, with nurses and doctors and everything necessary to take care of a very considerable group of children, into the Northern Peninsula.

"After studying the situation for some time it was decided that the University and the State Society enter into a contract with the Couzens' Fund with a view to establishing a medical center in northern Michigan. That was the suggestion that was decided upon. A clinic building would be erected for purposes of diagnosis and for treatment, and the work would progress under the auspices and control of the Department of Post-Graduate Education of the University of Michigan and the Michigan State Medical Society. At regular intervals during the year clinicians

Acute Articular Rheumatism

The traditional value of the salicylates in acute articular rheumatism is best obtained when a pure, natural salicylate is used and especially when it is combined with a balanced alkali. Such a preparation is ALYCIN—a combination of Merrell's Natural Salicylates and a balanced alkali. Wherever the salicylates are indicated, Alycin gives the most satisfactory response.

and teachers would be sent there and diagnosis would be made; demonstrations would be made upon the clinical material afforded. In that way they would establish, really, an extension of the University and of the State Medical Society.

"We know that very often, no matter how laudable the purpose of these large foundations may have been, yet with large sums of money at their disposal as public servants the personnel have gone about to do a certain duty, and in their zeal they have often overrun what we regard as the proprieties of medical practice. We have every assurance that that will not be done in this instance because the professional activities are entirely under the control of the department which I represent in the University, and under the control of the committees among the profession locals, and, of course, the profession in the State."

Dr. Bruce reported: "I met with the Society in groups at the Soo. Every member of that district was there except one. At Marquette we had an attendance of about 50 or 60. Each of the other meetings was attended by proportionate numbers. There was universal accord on this matter. They all appointed committees to work with the Fund in the prosecution of this work."

COUNCILOR DISTRICT MEETINGS IN NEW JERSEY AND PENNSYLVANIA

The December number of the Journal of the Medical Society of New Jersey contains a stenographic report of the Conference of Secretaries and Reporters of the County Societies of New Jersey, held on November 5, 1930, in Trenton. One subject discussed was a proposal to hold Councillor District meetings. New Jersey has five councillor districts which are analogous to the Eight District Branches of the Medical Society of the State of New York; but unlike those of New York, the New Jersey districts do not hold annual meetings, although the Fifth, consisting of the southernmost counties, has held meetings in 1929 and 1930.

The arguments for Councillor District meetings were presented by Dr. Walter F. Donaldson, Secretary of the Medical Society of the State of Pennsylvania, which is divided into eleven Councillor Districts, each of which holds an annual meeting. Dr. Donaldson described one function in which the councillors are members of the Board of Trustees of the State Society, as they practically were in New York before a separate Board of Trustees was organized in July, 1926. Dr. Donaldson said:

"In Pennsylvania, the members of our Board of Trustees are also Councillors. You, of course, have a Board of Trustees in your State Medical Society and I do not need to tell you how great

(*Continued from page* 48—*xii*)

are their responsibilities. In Pennsylvania, our Trustees conduct all of the interim activities of the State Society,—I mean in the period between annual sessions of the House of Delegates. Therefore, the members of the Board of Trustees are familiar with the activities of all standing or permanent committees of our State society; with the conduct and publication of our monthly journal; and with the financial problems of the society, because all of the finances are handled by the Board of Trustees, even those originally created by the House of Delegates. Our Board of Trustees meets regularly three times a year, and at the call of the Chairman when necessary. At these meetings all standing committees, which later on report to the House of Delegates, are expected to make reports of progress, or if they desire suggestions or advice, to come before the Board of Trustees. The reason I mention this fact is that the members of our Board of Trustees are also Councillors, and through this familiarity with conduct of the business of the State Society each one of these trustees, as a councillor for a district, is kept familiar with what is going on in the State Society between annual meetings. And since his duties as a councillor require that he must conduct at least one meeting annually in his district, he will take to that group of component societies the very latest developments in relation to problems that are before the Board of Trustees."

Dr. Donaldson also described a system of District Censors, as follows:

"Among the officers of our State Society are not only the Board of Trustees who are also Councillors, but we have District Censors. A district censor is a member of a component county medical society who has been recommended, or nominated, to the House of Delegates at the annual meeting of the society by a component society; and, of course, he has always been elected by the House of Delegates. Among our State Society officers are sixty-two district censors. Their duties are not heavy, but are largely of a judicial character. Members who have been disciplined by component county societies and who wish to carry their case further, must do so through the district censor of the county society. He in turn will call a meeting of the district censors of other county societies in his councillor district."

Dr. Donaldson then discussed the program of an ideal district meeting as follows:

"We always open with a report from each district censor, limiting that report to about sixty seconds. In that time, he reports the number of members, the number that have died since the last meeting, number of scientific meetings held, and the interest or lack of interest that has been shown.

(*Continued from page 50—adv. xiv*)

"The second subject of an ideal district meeting is a paper on the history of some county society which becomes the property of the councillor in charge of the district, who in turn sends it to our archives of the State Society; and in that way we are slowly accumulating material for what we trust will be a worthwhile history of the Medical Society of the State of Pennsylvania."

The third feature of the ideal program is an address by the President of the State Society, and lastly a scientific session. Dr. Donaldson concluded as follows:

"The State Society contributes in no way to financing the social features of such a meeting. We expect every man to pay for his own dinner, and as the dinner is usually at a hotel or country club, there is no additional expense for a place of meeting; so there is not much expense to consider.

"As for attendance, I haven't time to analyze that, but I will say that the attendance is never disappointing. At the Valley Forge meeting there were one hundred and twenty-six in attendance. That many men gathered together makes a very inspiring group. At the district meeting held in Pittsburgh recently, there were one hundred and seventy-six at the afternoon meeting and two hundred and twenty at the night meeting. Of course, you might expect a much larger attendance than that from a councillor district that has one society as large as the Allegheny Medical Society, but an audience of one hundred seventy-six to two hundred and twenty is well worth talking to."

The meeting adopted a lengthy resolution in favor of establishing district meetings, and then followed a long discussion as to the details of starting the meetings,—whether they should be controlled by the county societies, or by the district councillors, or by the State Society. It was finally decided to leave the organization of the meetings to the councillors and the county secretaries and reporters.

WOMAN'S AUXILIARY OF MICHIGAN

The annual meeting of the Woman's Auxiliary of Michigan was held on September 16, 1930, in connection with the annual meeting of the State Medical Society. The activities of the Auxiliary were set forth by Mrs. Mundt, of Illinois, a Director of the National organization, as follows:

"Mrs. Mundt suggested that we enlighten our-

THE PROFESSION RENDERS ITS VERDICT ON THE VICTOR SHOCK-PROOF

Only the Victor Shock-Proof permits this

Illustration shows the Victor Shock-Proof X-Ray Unit, Model B, applied in a manner never before possible with any other type of x ray apparatus Assume this to be an emergency case, where a radiograph of the head is desired, and the condition of the patient preventing transfer to the x ray table. With this Victor Shock-Proof Unit, it is only necessary to raise the table top, wheel the patient's cart into position, focus the tube (within the shock-proof head), and proceed with the making of the radiograph A fluoroscopic examination may be done with the same facility

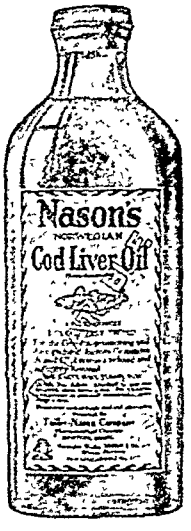
Bear in mind, that in such procedure there is no danger of the high voltage system coming in contact with you or your patient, as the Victor Shock-Proof Units are, as the name implies, 100% electrically safe

"The Shock-Proof has given me a new conception of the *use of x-ray technic*"

"I HAVE been the proud possessor of the Victor Type A Shock-Proof X-Ray Apparatus for almost one year and can give unqualified endorsement of its capability and ease of handling," writes a Missouri physician.

"As a general practice in which it has been used, it has been revolutionary in the excellent quality of pictures, unusual adaptability to any position or angle, and in the feature of electrical safety. It is especially satisfactory in fluoroscopy above or under the table, or for the unlimited positions at any conceivable angle or across table. The apparatus is easily and readily changed to meet the desired setting, even by a very small technician as I happen to have.

"The shock-proof apparatus has given me a new conception of the use of x-ray technic. To say that I am highly pleased with my outfit is scant praise . . . I can gladly recommend this apparatus to any prospective user of x-ray equipment."



Let us send you an illustrated brochure and tell you where in your vicinity you may see the Victor Shock-Proof in use.

selves as to bills coming up in the legislature, see that our members are given strategic positions in clubs where bills are discussed so that both sides of the question are presented; our auxiliaries should have occasional meetings with the medical societies; keep our eyes open to see to what organizations we are contributing, and in clubs know for whom we are voting, and whether they are friendly to the medical profession. She suggested that we let our friends know that the American Medical Association broadcasts health talks, and do what we can to suppress quack health programs; suggest to club women that they use the package libraries from the health departments; place Hygeia instead of Physical Culture in offices, also that we should read the Medical Journal ourselves; be sure to enlighten ourselves regarding State medicine; read and know what medical science has done in stamping out disease. 'We can do much toward spreading information to the benefit of medical legislation. Let us join hands in helping our own profession.'"

The President of the Auxiliary reported that it had 648 members, which she contrasted with the membership of Pennsylvania, 1,894; Texas, 1,173; and Minnesota, 774. The National organization has 10,220 members in 37 organized states.

THE ENGLISH HEALTH INSURANCE LAW

Dr. Henry O. Reik, Editor of the *Journal of the Medical Society of New Jersey,* gave an address before the New Jersey Conference of County Secretaries and Reporters on November 5, 1929, as recorded in the December issue of the *Journal.* Dr. Reik referred to the articles in the NEW YORK STATE JOURNAL OF MEDICINE for July 15, August 1 and 15, and September 1, describing the proposals for a general medical service proposed by the British Medical Association, and then said:

"I would like to add, regarding the Health Insurance Law in Great Britain, that I happened to be in England when that was instituted, and learned afterward that physicians were not so bitterly opposed to that law as we were led by published reports to believe. I have been surprised to read from time to time in some of our medical journals that 'the profession has been ruined by that law.' I am told by English practitioners that the bill has not been such a horrible affair. It was fought by the profession for a time, but if it were put to a vote of the British Medical Association today whether they would hold to the law or go back to the old conditions, they would vote to hold to the present law. But

(*Continued on page 55—adv. xix*)

(*Continued from page 54—adv. xviii*)

they do want something better than they have, and they have at last done what I think would have been the best thing to have done in the beginning, and what I think will be the best thing for us to do to-day in advance of any State Medicine Act being passed for us. The British Medical Association has proposed that the Government shall extend the national health insurance law, which at the present time only covers 15,000,000 members of the population, to the entire population of the country, and in such form that it may embrace anything that may be necessary in preventive as well as curative medicine There is a widespread misunderstanding in this country that the British law took away from the individual the right to choose his doctor. It did not Under the present law the individual can choose his own physician. The physician is not, on the other hand, compelled to accept the patient. If he does not want to attend an individual or his family, he can decline and the panel board makes some other arrangement. It is working smoothly. The doctors are now getting payment in many cases where they previously got nothing for their work. There is some abuse of the law, of course. It works very much like our Workmen's Compensation Act. I suppose each of us could find something to criticize about that law in New Jersey, but on the whole the medical profession is certainly better off than it was prior to the passage of that law, when physicians had to do much work for which they received no pay."

GROUP LIABILITY INSURANCE IN FLORIDA

The November number of the Journal of the Florida Medical Association, Inc., contains the following circular letter:

"At the last meeting of the Florida Medical Association, the present Executive Committee was authorized by the House of Delegates to arrange with some insurance company for a group malpractice insurance policy which would be available for any member of the F. M. A. who might desire it, provided such insurance could be obtained for our members at premium rates less than those charged for individual or small group policies.

"Your Executive Committee has made a careful study of malpractice insurance as it is now carried by the various members of our Association. Also many conferences have been held with representatives of several responsible insurance companies.

"An arrangement has finally been made with the United States Fidelity and Guaranty Company, of Baltimore, for a group policy which will

Here is a Calcium—

immediately assimilable, administered orally—and that actually tastes like Chocolate Peppermint

Ōlajen
TRADE MARK REGISTERED
COLLOIDAL

Not an ordinary calcium with a would-be chocolate disguise, but a sound and ethical preparation utilizing a vehicle of novel form to combine calcium and other physiologic salts with lecithin in a colloidal base. Extensive clinical experience backed by laboratory tests shows that Olajen is a serviceable agent in conditions of calcium deficiency.

When the normal calcium is low,

When the patient is undernourished,

When bodily resistance must be raised,

When bronchial affections "hang on" and sap vitality—prescribe Olajen. One teaspoonful to be eaten after meals and at bedtime.

Clinical results will demonstrate to you, often more rapidly than expected, that there is a definite therapeutic reason for offering Olajen in its colloidal chocolate vehicle.

Olajen contains per 8 oz.:

Calcium lactate	12 gr.
Iron phosphate	12 gr.
Sodium phosphate	12 gr.
Potassium bi-tartrate	12 gr.
Lecithin	4½ gr.

in a colloidal, nutritive base.

Olajen, Inc.

comply with the requirements of the House of Delegates.

"Any member of the Florida Medical Association will be eligible to become a member of this group. In every form of policy there will be a saving in premium rates. This saving will be less for those men who have formerly been insured in small county groups. For those who have been carrying individual policies, it will naturally be greater, amounting in some forms of policies to over 40 per cent.

"This service will be available October 14th, next. Individual policies must be taken out through local representatives of the United States Fidelity and Guaranty Company in your county. Further information may be obtained from the secretary of your county society."

POST-GRADUATE EDUCATION IN MAINE

A plan for Graduate Education in Maine is set forth in the following statement in the *New England Journal of Medicine* for October 30:

"The Board of Directors and the Medical Staff of the Central Maine General Hospital under the auspices of the Harvard Medical School Courses for Graduates are developing a new plan of post-graduate medical education for districts removed from the larger medical centers. Previously, it has been possible for physicians to obtain graduate instruction only in Graduate schools associated with the larger Universities. Such instruction is specialized, expensive, and means that the physicians must be absent from their own hospital centers for a considerable period of time. At best, such graduate instruction is available only to a limited number of practicing physicians.

"The new plan adopted at the Central Maine General Hospital in Lewiston has as its chief aim the education of the staff members and physicians associated with the hospital. It hopes to accomplish this by conducting teaching clinics at the hospital under the auspices of the Harvard Medical School Courses for Graduates. The Board of Trustees has voted $1,000 to put this project into operation during the current year and has approved the following plan:

"1. That ten post-graduate clinics be held at the Central Maine General Hospital either monthly or bi-monthly as may be recommended by the graduate teaching service. A plan to place these clinics under the

auspices of the Graduate Courses of the Harvard Medical School is approved

"2. That Dr. Soma Weiss, Assistant Professor of Medicine at the Harvard Medical School, head this service and recommend the associates.

"3. Objects:

"A. To elevate the standards of medical practice in the community and to keep these abreast with those of the larger medical centers.

"B. To provide adequate consulting services to patients, equal to those of large medical centers, which can otherwise be obtained only at a great cost and effort.

"C. To create a Medical Center about the Central Maine General Hospital for the neighboring districts."

SOCIALISTIC MEDICINE IN TENNESSEE

An editorial in the November Journal of the Tennessee State Medical Association discusses the socialistic tendencies in medicine, as follows

"It is most unfortunate that doctors' fees are always thrown into the jumble of costs of being sick Doctors may be blamed or credited for whatever effect their charges and collections have on the situation and no more. Most all the speakers and writers of recent months make no attempt to clarify these points in the minds of the readers. The lay reader is left with the unfortunate impression that all of the services cost too much and the doctor alone is to blame. This is not only unfortunate—it is unfair both to the doctors and the public. It may lead to rash action which would not only bring regrets but would be difficult to correct.

"The attitude of some leaders in business is so inconsistent as to be striking. They seem to favor the principles of socialism as applied to affairs other than their own business. This bit of inconsistency is the biggest danger that lies out in front of us.

"Every one recognizes the importance of the relationship between health and good food, good homes, good clothing, good blankets, decent hours of work and recreation; yet the very men who see advantages in medical socialism would be most violently opposed to these other necessities being supplied by socialistic methods."

KEEP the Blood Pressure

Many drugs are capable of lowering blood pressure but few of *maintaining* reduced pressure sufficiently long to benefit the patient. Experiments prove that lowering of tension produced by the drugs classified as vasodilators is only a matter of minutes or hours.*

But blood pressure can be lowered, and kept down safely and surely, by administering a synergistic combination of approved vasodilators (sodium nitrite, potassium nitrate and nitroglycerin) in combination with Cratægus Oxyacantha—Pulvoids Natrico. Although incapable of lowering blood pressure alone, Cratægus Oxyacantha has the unique property of aiding in maintaining the lower level brought about by other means.

Try Pulvoids Natrico for yourself and check its results against the cold figures on the sphygmomanometer. Prove to your own satisfaction that the reduction of blood pressure they effect is not a matter of *minutes* or *hours* but of *days*.

*Effect of amyl nitrite lasts 7 minutes; nitroglycerin 30 minutes; sodium nitrite 2 hours; erythrol tetranitrate 4 hours; mannitol hexanitrate 5 hours.

(*Continued from page 57—adv. xxi*)

The article closes with the following paragraph, which is printed in italics in the Journal:

"We will repeat again, business leaders may force socialism into medicine. If it does, medicine in turn will socialize the balance. This one type of human service will not be rendered under a socialistic scheme of operations and others remain unsocialized."

COUNTY HEALTH DEPARTMENTS IN IOWA

A leading article in the November number of the Journal of the Iowa State Medical Society describes the new law regarding county health departments, and says:

"The Forty-third General Assembly of Iowa gave us a law granting permission, or making it a legal possibility for any county board of supervisors to appropriate funds for a county health unit.

"In the political organization of our State government the township or municipality constituted the unit for all things governmental.

"It was found in 1925, that the county had no legal right to appropriate funds for county-wide health work, since such function was delegated wholly to townships and municipalities. Prior to 1925 there had been two county health units organized in Iowa but both were discontinued on account of this legal opinion.

"The Iowa county unit health law delegates to the county board of supervisors the legal right or privilege, 'by their own resolution, or by mutual agreement with any local board or boards of health of their county' to adopt the county health unit plan..

" 'When the county health unit plan is adopted a county board of health shall be appointed by the county board of supervisors to guide and direct all public health activities within the county.'

"The county board of health shall consist of not more than eleven members, three of whom shall be members of the county medical society. The others may include representatives of local boards of health or representatives from boards of education or any other organization interested in public health activities.

" 'All financial expenditures shall be approved by the board of supervisors. The county board of health shall serve as such without pay.'

"The State Commissioner of Health is charged with the two following duties:

"1. To assist in the investigation of all public health activities carried on in the county and, advise the county board of health and the county

(*Continued on page 60—adv. xxiv*)

Curiosity GAVE THE WORLD A NEW AND IMPORTANT MEDICINE ... PHYSIOLOGICAL STANDARDIZATION MADE THIS MEDICINE UNIFORMLY POTENT ... ...

OLD MOTHER HUTTON, the Shropshire herb-woman, guarded her secret jealously Had not her herb tea relieved an Oxford dean of his dropsy, when all other remedies had failed? To satisfy his curiosity, Dr William Withering sought out the old woman, nearly 150 years ago At first she stubbornly refused to talk to him. But finally one argument prevailed. There was the clink of golden sovereigns in Mother Hutton's palm, and the cherished recipe was his!

Withering saw that the crudely written scrawl called for twelve common herbs and plants. After long and patient trial he found eleven of them medicinally worthless. But in the twelfth, the purple foxglove, he found a new and powerful drug, now more commonly known as digitalis.

Physicians welcomed Withering's contribution to medicine, but they soon found that the use of digitalis was attended by a serious difficulty. Extracts made from the drug were by no means uniform in potency. Some were too weak, others were much too strong for safety.

For over a century, physicians and pharmacists grappled with the problem of making uniform extracts of digitalis. Then, in 1898, exactly 113 years after Withering's discovery, the Parke-Davis medical research laboratories announced the first *standardized* tincture of digitalis.

... ...

Parke, Davis & Company is justly proud of the part it has played in introducing, developing and extensively applying the principles of chemical and physiological standardization. No product leaves our laboratories until there have been applied to it all the tests that scientific investigation has found necessary to determine its purity and potency as a medicinal agent.

THE WHITE HOUSE CHILD CONFERENCE

The December issue of *Colorado Medicine* contains the following excellent editorial on the White House Conference on Child Welfare:

"The main recommendations of the White House conference are very largely colored by the report of Section III of the conference. This section, on Education and Training, furnished an extremely well organized and constructive program. We would that as much might be said of all the sections. The section on medical service was handicapped by the fact that the related committees had not finished their task, and even after the conference had been called from all parts of the country were compelled to meet in camera, closing their doors on the first morning of the conference to the assembled delegates. In the section on public health, committees had indeed reached a program, but it contained so much well accepted material, as that milk is a valuable food and should be used more freely, that its more important suggestions are in danger of being overlooked.

"Among these latter we note emphasis upon the value of the county health unit and the demand for increased appropriations for public health services from federal, state, local and private funds.

"An excellent suggestion, coming from this section, is the recommendation to County and State medical societies to appoint advisory committees

(*Continued on page 61—adv. xxv*)

(*Continued from page 60—adv. xxiv*)

who shall confer with official health organizations.

"A lively dispute which has been spoken of as 'unfortunate' developed in the sub-committee to study reorganization of federal health services. The sub-committee had recommended that the maternity and infancy work of the Children's Bureau of the Department of Labor be transferred to the Public Health Service Miss Abbott, who was a member of the sub-committee, wrote a dissenting minority report which was omitted from the official volume of preliminary committee reports.

"The delegates who attended the first meeting of the conference in this particular sub-section were quite obviously and militantly on Miss Abbott's side. The chairman made every effort first to prevent the delegates from speaking to the subject at all, and then to block any effective expression of their views. But the weight of the very much consolidated women's organizations and the social workers from all over the country finally prevailed, and the disputed recommendation has been referred to a continuation committee for unanimous agreement.

"The dispute may be a most fortunate incident if it should draw the attention of the medical profession to the existence of organizations that have definite interest in child welfare and in its political organization

"It is quite probable that the proposal of the majority of the sub-committee was sound. What was evident was that the distinguished medical men on the committee were quite unaware that their suggestions were of interest to several million women, to many organized social workers, and even to organized labor. Their attempt to muzzle the representatives of these interests showed even more clearly how far they are from political common sense. A protest which might have been temporary and futile is now in danger of becoming an emotionally debated issue in every corner of America.

"There is a moral in this dispute that is applicable elsewhere. The problems of medicine are becoming and must increasingly become matters of public interest. Unless we have not only a rational programme for meeting medical social needs, but have also persuaded the public of the advantages of our programme, we may expect to find our influence in future legislation of astonishingly small account."

THERAPEUTIC ALMANAC

JANUARY FEBRUARY

Months of winter-coughs and colds—infectious and febrile diseases. Acidosis predisposes to them—aggravates them. The right alkaline combination has a threefold function: to act as antacid, to liquefy the mucus; to produce diuresis, to reduce the fever.

Rx ALKA-ZANE

A teaspoonful in a glass of water, taken after effervescence has subsided, as often as the patient desires a cooling drink.

Note—Alka-Zane combines the carbonates, phosphates and citrates of sodium, potassium, calcium and magnesium. No sulphates, tartrates or lactates; no sodium chloride.

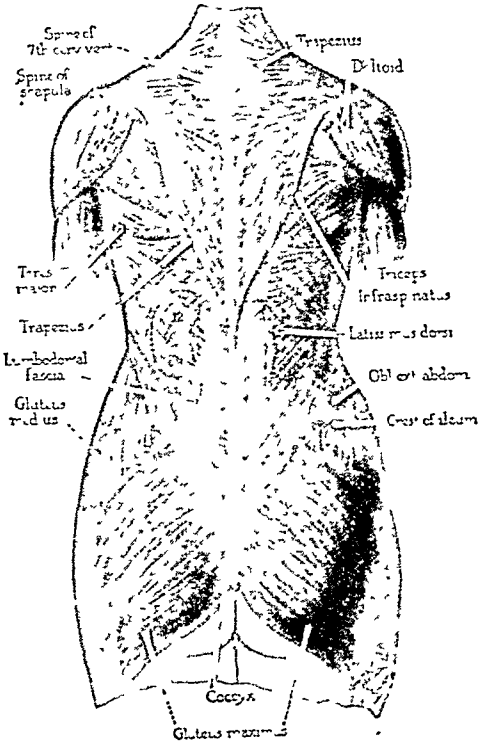
COLLECTION AGENCIES IN WISCONSIN

The *Wisconsin Medical Journal* for December has the following editorial comment on collection agencies:

"More and more complaints are coming to the desk of the secretary of the methods and service of collection agencies.

"A recent case involved a justice court suit brought by a collection agency upon a fifty-dollar physician's account. The agency entrusted the matter to a clerk, who was not a lawyer, whereas the defendant was represented by an attorney. The services had been rendered more than two years before the suit, but nevertheless the attorneys for the defendant set up a counterclaim for $200, the limit of the justice's jurisdiction, for alleged malpractice.



"The physician knew that the counterclaim for malpractice, asserted for the first time after the suit, was unfounded, but knew also the loss of time and unpleasantness attached to defending such a claim, and instructed the collection agency to defend with the statute of limitations. But the clerk did not know how to do this, with the result that the patient's uncontradicted testimony was taken of the malpractice, and judgment of $150 and costs was about to be entered against the physician.

"Just in time, the physician became aware that something was wrong, and consulted his State Medical Society, who immediately placed the matter in the hands of a competent attorney. This attorney secured delay, straightened out the procedural mix-up, and got the counterclaim dismissed and judgment entered for the physician for fifty dollars and costs.

"It is just as logical for the sick to go to laymen for medical relief as it is to place legal matters in the hands of a lay collection agency.

"So great need does there appear to be for some reliable agency in the collection field, that will have an understanding of physicians' accounts and competently handle them, that the entire matter is being investigated to ascertain if a practical solution can be worked out."

WOMAN'S AUXILIARY IN MINNESOTA

The December issue of *Minnesota Medicine* has the following editorial on the Woman's Auxiliary.

"The Woman's Auxiliary of the Minnesota State Medical Association was one of the first auxiliaries to be founded. The question of the advisability of starting an auxiliary in Minnesota was fully discussed previous to its organization and the step was taken with the approval of the State Medical Association.

"While the members of an auxiliary have few common interests compared to those of a medical society, an active auxiliary can undertake certain well worth-while activities.

"Perhaps one of the most important functions of a medical auxiliary is the entertainment of visiting women at the time of medical conventions. This applies, of course, to the units in the larger cities, and the entertainment of the visiting women at the recent International Assembly in Minneapolis is a case in point.

"Fully as important a function is the opportunity an auxiliary has for disseminating facts about medicine through its contact with various women's organizations. We are inclined to shut our eyes to the importance of using every channel possible to counteract the vigorous and often malicious propaganda being foisted upon the public by anti-vivisectionists, anti-vaccinationists and similarly minded individuals. The false reasoning and illogical conclusions reached by certain well-meaning, but perhaps often fanatical individuals is certainly in opposition to sane medical progress and detrimental to the public welfare. Continuous, not spasmodic effort to inform the public through every possible agency must be made to counteract the various anti's who seem to be tireless in their energy.

"Legislative activities are mentioned as one of the functions of an auxiliary. Lobbying is out of the sphere of women, but members of an auxiliary can be informed as to choice of legislators and can disseminate such information.

"We approve the aims of the Women's Auxiliary of the State Medical Association which are enumerated in this issue of the *Journal*, and we offer our assistance in every way possible.

PUBLIC HEALTH WORK IN OHIO

The December number of the *Ohio Medical Journal* has the following editorial description of local health departments in Ohio:

"At the annual conference of Ohio health commissioners with the State Department of Health, held in Columbus the third week in November, questions and problems relative to public health work in Ohio were discussed and the official health work being carried on in the state appraised.

"Ohio ranks high among the various states in its organized, official public health activities.

"Eighty-six of the 88 counties of the state have full or part-time public health services.

"Forty-four counties have full-time services. Seventeen cities have full-time services, combined with county service, and 18 cities have full-time services, exclusive of county service.

"All of the 86 county or joint county-city health commissioners of Ohio are physicians.

"However, of the 75 cities of the state having health services independent of county services, 21 employ health commissioners who are not physicians.

"It must be admitted that some good public health work may be carried on in some cities by commissioners who are not physicians and who have little or no knowledge of the medical sciences. On the other hand public health work in other cities has been decidedly inefficient, due, no doubt, to the fact that the director of the service is lacking not only in executive ability but also in knowledge of the fundamental sciences which play a principal role in curative and preventive medicine."

DERMATOLOGY IN RELATION TO METABOLIC DISTURBANCES*

By WALTER JAMES HIGHMAN, M D, NEW YORK

TWO groups of manifestations occur in any diseased organ,—manifestations peculiar to that organ, and manifestations in that organ reflecting a general disturbance Thus the skin is affected with local diseases and with diseases representing participation in a general process It is not always possible to refer an eruption to its proper class on inspection Frequently enough, even after painstaking study, it cannot be done

Dermatology, until a comparatively short time ago, seemed to be peculiarly dissociated from internal medicine The precise ties between the disturbed skin and disturbed body it envelopes were vague Today they are not yet definitely known, but an insight into the relationship has been gained If the curve of dermatological growth were traced it would be found at a dead level until its rise in the era of Willan in England, then a drop until Hebra and his school in Vienna brought it to the level which is the jumping off place for every enterprise in modern cutaneous medicine Isolated names in English, French and German speaking lands caused small elevations in the line between these two masters Willan's genius was mainly biological, Hebra's mainly that of a classifier Willan was an internist, Hebra an externist, in his leanings The value of Willan's efforts was lost partly because of his untimely death, partly because the methods and knowledge of an internist were necessarily restricted over a century ago The clinical genius of England was reflected in Willan

Hebra was an acute observer, a stupendous reader and an original thinker He achieved for dermatology what Darwin did for biology He collected, studied, arranged and classified dermatoses But he lacked Darwin's philosophic talent for crystallizing out great principles His was a card index mind Using arsenic, as he did in treating lichen ruber, he even failed to see the significance of his own gleanings Nevertheless, his was a signal contribution to dermatologic progress for he supplied the alphabet of the specialty His classification today stands unchallenged, and if he lacked subtlety, he at least had force No one is a dermatologist who does not start out with a complete understanding of Hebra His language is the Esperanto of the specialty The problems of dermatology are those of understanding, explaining and rearranging the conditions he isolated and named, according to the enlightenment of modern methods of medical investigation

If Hebra's work resulted in an absurd vocabulary, it is absurd only in the sense that his nomenclature may become obsolete or inaccurate as progress makes it so Inherently, in relation to his era it was serious and important Few men have had their names identified as Hebra's is, with an epochal moment, the plotting of the point of departure at which the future path of a science or art is indicated and indicated clearly Hebra's immediate successors began the journey, notably Kaposi Hebra's school is the dermatologist's alma mater To belittle Hebra would be like belittling Euclid because an Einstein has been born, or Hippocrates because there has been a Claude Bernard, or Plato because a Spinoza came later Hebra could not be a dermatologist, as we today can be, in terms of parasitology, histology serology, immunology, biochemistry and endocrinology, because some of these fields were then scarcely opened and others not yet discovered If dermatology fifty years ago was scarcely more than an objective branch of medicine, a series of labels for skin pictures, general medicine was little better Up to then, medicine too was merely an art, the successful application of which depended simply on combining a patient's story with observation of physical signs gathered by the examiner's eye ear and fingers The nearest approach to laboratory study of a disease was urinalysis In dermatology only the eye and fingers were required

* Read at the Annual Meeting of the Medical Society of the State of New York at Rochester, N Y June 4 1930

are still ignorant of those that cause the exanthemata. Such a fact does not negate the infectious hypothesis nearly so much as that there is no valid evidence of transmission from person to person. Indeed, there is more logic just for this reason in favoring the metabolic theory. The effect of arsenic alone supports it, although this metal might equally function as a parasiticide were the disease due to a general infection. On the other hand, none of the huge amount of investigation purporting to prove its metabolic origin, notably in the domain of nitrogen chemistry is convincing. In spite of Schamberg's painstaking studies, neither his findings nor therapy based thereon are conclusive. What is instructive in our research on psoriasis is that neither the doctrine of its internal or external origin has been overthrown nor maintained by work designed to sustain or tear down either point of view. The mere fact that in a large minority of psoriatics evidence exists of disturbed nitrogen metabolism does not signify that such a disturbance either explains or is related to the disease. Indeed, no therapeutic policy founded on any such assumption, whether as to drug administration, diet or other regimen, affects the disease without proper local treatment. Moreover, local treatment alone is often efficacious. What the meaning is of the frequent success of autoblood injections in this disease is still a mystery. Nevertheless, the impression is justified that psoriasis is a metabolic disease, if only because of its not infrequent relation to arthropathy. Our failure to prove the fact may be lack of adequate methods of investigation which the future may amend.

Much of what has been said about psoriasis applies to eczema. The origin of eczema, if external, may be infectious or due to chemical or physical agents; and if internal, to infection or metabolic causes. In point of fact all these views are correct. The essential lesion of eczema is the vesicle. The lesion which is a response to most agents is the erythema. Next comes the wheal; and third, the vesicle. Each one of these lesions indicates a single process, but the number of excitants of each process is huge. Therefore a great many different substances and conditions may provoke eczema. Some eczematics get the eruption from only one cause, others from several. It is a dermatologic commonplace today that eczema and dermatitis venenata are identical. The history of how this view became now almost universally adopted would serve as a special thesis, but the fact must be taken for granted. It will be sufficiently substantiated by Norman Walker's case of primrose dermatitis outlining an experience no dermatologist today has lacked. A lady with chronic eczema recurring for years under given conditions of life in her home, was found to get the eruption whenever she came near primroses, for which she had a great fondness. When this fact was determined, and the primroses were eliminated from her surroundings, she was cured. This is the foundation of our present understanding of eczema, substituting other precipitants for primroses in the story.

In the past eczema was recognized as similar to or identical with dermatitis, dermatitis being defined as a form of the syndrome in which the cause was known, eczema as one in which it was unknown. About seventeen years ago, I first maintained their identity in this country, and ten years later adduced convincing proof of the fact, at about the same time that Bloch, now of Basel, published more and better conceived studies proving the point. For the moment let us regard eczema in the old light, as dermatitis of unknown origin, and test the validity of the concept "unknown." Unknown etiology assumes the character of widening hypotheses with the growth of medical knowledge. Thus at first eczema was considered gouty, later parasitic, then metabolic, nervous, anaphylactic in origin. It was variously associated with distinctive periods in human life, childhood, adolescence, the climacteric, senility. It was terrifically overnamed. The most fantastic theories, dietetic, medicinal, local and the like were applied to its treatment. In recent years Schamberg attempted to prove its relationship to excessive blood uric acid; MacGlasson to too much blood sugar.

Whatever else is true of eczema, this fact stands out, that there are people who readily get the disease. This was noted fifty years ago by Besnier, who called such individuals eczematics, and who stated in the vivid manner of the French: "There is no eczema, there are only eczematics." What this means is that if the eczematic be not exposed to something that provokes the eruption he is free of it. Of course, the same is true of any disease, but it requires intelligence to isolate a principle, and as soon as a principle is accepted as a law it seems trite. Of fifty people exposed to rhus or bichloride or some other substance, only relatively few will respond as eczematics. These few might not respond to primrose or soap, as still another group might. In short, eczematics are peculiarly susceptible to certain things. Call this idiosyncrasy, allergy, hypersusceptibility, atopy or by any other term. The point is that the eczematic is responsively prepared to react to certain agents in a consecutive way.

Such responsiveness may be congenital or acquired, may be due to sensitization or not, may, in the last analysis, represent a skin locally responsive, or responsive because of some internal disturbance. If the last be so, and this is still subject to demonstration, then metabolic or internal infectious agents must be considered as

possible actors in the drama. It is true that eczema may disappear when diabetes is controlled; or upon removing a kidney infected with the colon bacillus after it had been reduced to a shell by a huge antler calculus, as in a case of my own. Needless to say, if the eczematic in some way stops being one he will no longer react to precipitants; allergens as they are now called. Thus, biologically, eczema may be considered a cutaneous response in a prepared individual to exciting causes. It is an exudative inflammation, acute or chronic, according to the consistency with which exposure to excitants is maintained, or the consistency with which the peculiarities conditioning predisposition persist.

In diabetes the curve of the latter is easy to trace. But in more instances, eczema has been ascribed to disturbed nitrogen than to disturbed fat metabolism, and to my mind on the flimsiest of grounds, namely, blood chemical studies; especially to hyperuricacidemia. This state in a case of eczema does not indicate inevitable cause and effect or even relationship. It is not present in more than forty-five chronic cases out of a hundred. Nor does a scheme of life based on the relief of such a disturbance relieve, to say nothing of cure, eczema. If, during, a hospital stay such a patient loses his eruption, it is more likely because he is away from the environment including the precipitant. A twenty-eight-year-old patient of mine who has had chronic, recurring, extensive eczema for fifteen years lost her eruption within a week after an appendectomy. Clearly a case of metabolic eczema! A relapse took place in her home a few days after she left the hospital. It was found to be due to soaps and household cleansing powders.

In fact, eczema must be studied by skin tests, the patch tests of Bloch and his school. Suspected agents are applied to the skin in several ways. The responsible ones provoke a local patch of eczema either at the site chosen for the test, or at a site previously affected. More and more chronic cases, with or without laboratory evidence of metabolic disturbances fall in this group. Thus the study of the disease today resolves itself into one of isolating precipitants. For future study, as methods are improved, is reserved that of predisposition, which is, of course, metabolic in meaning, whether the disturbance be congenital or acquired. For the moment eczema must be regarded as allergic in nature, but not in name, for allergy and all kindred states express the ancient knowledge that one man's meat is another's poison. We know now that eczema can often be explained by exposing an eczematic experimentally to suspected agents, thus giving him eczema. It is a simple concept and requires none of the miasma of pseudoscientific verbiage to adorn or befog it.

More precise evidence of the nature of the foregoing is found in eczema due to pathogenic fungi. The details are intricate, and to elaborate them would prolong this paper without adding to its substance. Suffice it to say that this type, still so widely ascribed to gout, uric acid and such other fantasies, actually reflects certain recognized laws of infection and immunity, and strikingly parallels the chemical types save that the source of the poisons is the fungi. This fact put the coup de grace on eczema due to dyshidrosis, and has limited, if not overthrown, belief that pompholyx or sweat gland eczema is in any way different from other eczema.

If prurigo, pemphigus, dermatitis herpetiformis were as common as psoriasis and eczema, undoubtedly they could be as intensively studied, and the principles already elaborated, and the knowledge acquired, would be similar in significance to what obtains, imperfect as it still is, in the two conditions in question. It remains to show that metabolic disturbances are not the key to psoriasis and are the key to eczema, without, in the latter, losing sight of their contributory meaning. But this is stating the obvious. No disease develops except on suitable soil, and suitable soil must reflect pathological conditions, these in turn reflecting metabolic alterations, however subtle with reference to our present methods of attack. This must apply equally to so superficial an infection as impetigo, as to so profound a process as pemphigus.

A moment's recapitulation! There are skin diseases definitely related to internal disturbances, metabolic disturbances if this be the preferred term. There is a larger group not demonstrably so related but in which the strong presumption of such a relationship exists. There is a still larger group in which the explanation of the eruption is simpler and referable mainly to outside factors, which, however, could not operate without that modicum of general derangement inherent in the concept of susceptibility. The second and third groups overlap. It is the duty of the expert, basing his clinical conceptions of dermatoses on the classification of Hebra and his followers, to be able to appraise them in terms of modern medicine, to know which are essentially to be regarded from the internist's standpoint, and which are not. My own reiterated conviction is that a dermatologist is an internist who knows skin diseases. I should prefer substituting the term cutaneous medicine for dermatology. It follows, however, that I am not taking sides as between dermatological externists and internists. There should be no such division. A good dermatologist belongs to both factions and should not be partisan. I contend, however, that in order to be able to approach a dermatosis as an internist it is necessary first to know when it is not of purely external origin.

Let me illustrate. An aged, retired physician

had a generalized itching eruption called eczema by a syndicate of his colleagues. One group advised him to cut proteids out of his dietary because eczema was due to nitrogenous foods; the other group emphasized carbohydrates correspondingly, for parallel reasons. The old gentleman was accommodating and tried to obey both groups at the same time. When he consulted me he had edema of the legs, anemia and other signs of inanition. His skin disease was scabies. The human problem was to nurse him back to health. The moral is virtually what this paper is dedicated to, namely, that internism in dermatology must be founded on clinical dermatology, and its application must be based on something more substantial than superficial.

It would be quite as bad to treat prurigo for scabies. The moral would be that the externist should be rather less of an externist than internist when occasion warrants. In short, a dermatologist must know the significance and bearing, as well as its limitations in practice, of general medicine in relation to skin diseases. No qualified internist can be at a loss to understand and apply every element of modern medical knowledge to his problem. A dermatologist must be all of this with a special knowledge of skin syndromes thereunto added. Thus in considering the relation of metabolic disturbances to skin diseases, the significance and limitations of the ideas involved are admitted, and no dermatologist who is not primarily a physician is worthy of the name. Conversely, may it be urged in closing, that no internist who essays the field of dermatology without being able to distinguish between scabies and eczema is justified in his temerity.

REMARKS ON THE SO-CALLED JAMAICA GINGER PARALYSIS: REPORT OF A CASE

By GEORGE WILSON, M.D., PHILADELPHIA, PA.

CONSIDERABLE interest has been aroused, especially by the comments in the daily press, about a peculiar form of paralysis occurring in certain southern states and presumably due to the drinking of Jamaica ginger. The first reports on this condition seemed rather alarming and the diagnosis was obscure. It appears worth while briefly to cite a case which I have had the privilege of seeing in consultation with Dr. John B. Deaver and through whose courtesy I am making this report.

CASE REPORT: A white, married male, age 45, was admitted to the Lankenau Hospital, Philadelphia on March 18, 1930, having come to Philadelphia from a part of Tennessee where the so-called "ginger" paralysis was prevalent. So far as his present condition is concerned the past medical history is negative with the exception of a record indicating the use of "corn liquor" for years,—it has been his habit to take from 4 to 8 ounces of this liquid daily.

On February 1, 1930, he developed a severe upper respiratory infection and in a few days, apparently because of laryngitis, he lost his voice. On February 18, not having recovered from his cold, he took four ounces of Jamaica ginger and repeated the dose the following day. The infection gradually subsided and the man felt in good condition until March first when he noticed that the left foot below the ankle was numb. Two days later a similar condition appeared in the right foot. Both of his feet and [illegible] and in five days he had no movement left in the toes or ankles. The condition in the lower extremities remained stationary for the next twelve days.

On March nineteenth he first noticed numbness in his hands and difficulty in separating the fingers. The numbness bothered him because he could not button and unbutton his clothes and he had difficulty in handling eating utensils. For one day at the onset of the trouble he had difficulty in passing the urine. He gave no history of difficulty in vision or hearing, he had no girdle sensation and lethargy was not a part of the symptom complex.

EXAMINATION: The pupils were slightly unequal, the right being smaller, but both reacted well to light and accommodation. The cranial nerves were normal. The biceps, triceps and patellar reflexes were present and top normal, whereas the achilles were lost. Plantar stimulation produced no response whatsoever and the abdominal reflexes were present but depressed. The finger to nose test on the whole was well performed although he occasionally missed the mark on the left side. As far as the motor functions were concerned an absolute paralysis existed in all movements of the ankles and toes although the power at the knees and hips was excellent. In the upper extremities there was slight weakness in separating the fingers but the grip was good in both hands and movements [illegible] rist were free and easy. The man had

no spontaneous pain in the extremities and squeezthe feet, calves and hands produced no discomfort. Sensation was carefully tested and the only disturbance found was for vibration which was lost below the knees. Pain, touch, heat, cold and position were normal. In the upper extremities sensation was normal save for a slight disturbance of position sense in the left hand. He appreciated objects with the hands correctly but had difficulty buttoning and unbuttoning his clothes. The spine showed no evidence of disease. The feet were bathed in perspiration and the man complained mildly of a feeling of heat in the affected parts. Mentally, the man was alert, intelligent and co-operative.

LABORATORY EXAMINATIONS: The urine, blood count, blood chemistry, blood Wassermann and the spinal fluid were essentially normal. Cultures made from the nose and throat showed gram positive diplococci. Rontgenograms of the sinuses and teeth were negative.

CLINICAL COURSE: The man was under observation for nine days and improved. The paresthesias and weakness were disappearing from the hands and the feet had begun to regain power when he returned to Tennessee

DISCUSSION

The condition in this patient was evidently multiple neuritis occurring in a man long accustomed to the use of alcohol who developed a severe respiratory infection and then took eight ounces of Jamaica ginger in twenty-four hours. As not infrequently happens in a person accustomed to alcohol, an infection or an added toxemia is frequently enough of an insult to the peripheral nerves to cause signs of irritation or of paralysis in them. The delay in the appearance of the symptoms after the infection and after the use of the Jamaica ginger in this case is not unusual in certain cases of multiple neuritis; for example, after diphtheria the symptoms of peripheral nerve involvement frequently do not come on for four to eight weeks after the throat has become normal. The condition herewith reported reminds one considerably of certain cases of post-diphtheric multiple neuritis in which in addition to the paralysis there is a loss of so-called deep sensation with preservation of pain, heat, cold and touch. I reported instances of such involvement in diphtheria.[1]

The role of the Jamaica ginger in producing the paralysis in the case under discussion was probably contributory; the peripheral nerves had been well prepared by the prolonged, though moderate use of alcohol, were further insulted by an infection and the ginger preparation completed the job.

As far as the differential diagnosis in this case is concerned it appears to be a clear cut case of multiple neuritis, the only other possibility being an atypical form of poliomyelitis. This latter diagnosis, however, is untenable.

Several reports exist in the literature of blindness following the use of Jamaica ginger. Woods[2] reported six cases some of whom showed in addition symptoms suggestive of multiple neuritis although the neurological reports were rather meager.

Jamaica ginger has long been used in dry areas for its intoxicating effects and it is frequently used by chronic drinkers to taper off from a prolonged debauch. It is interesting in this connection to quote an article from the Baltimore *Sun*, November 16, 1898.—"There were two deaths in Oxford last week caused by drinking Jamaica ginger, used as a substitute for whiskey in dry places. The first to die was one, Terry, a peripatetic individual, who spent most of his time in Oxford. It is said he has a wife and children, but their residence is unknown. John Cousins, a permanent resident of Oxford, was the other victim of this pernicious habit.

Thomson[3] reported a similar case to those of Woods but a year previously. DeSchweinitz in discussing Thomson's paper remarked it was the first case of toxic amblyopia following the use of Jamaica ginger of which he had knowledge. He also said that he had been informed that people in the northern part of Pennsylvania who could not obtain whiskey were in the habit of indulging excessively in the use of Jamaica ginger.

It is likely that the toxic effect of Jamaica ginger is due in a large measure to the methyl alcohol which it contains. Methyl alcohol acts as a direct poison to the optic nerves and also to the peripheral nervous system.

POST-OPERATIVE CARE OF ABDOMINAL CASES

THE Buffalo Surgical Society met on February 18, 1930, and held a round table discussion on the topic "Post-Operative Care of Abdominal Cases." Twelve concise papers were presented by Fellows who were known to have original ideas on the several topics—Emesis, Pain, Thirst, Flatus, Fear, Constipation, Embolus, Ileus, Peritonitis, Hemorrhage, Secondary Infections, and The Stethoscope in Post-Operative Care.

These papers are printed in the order in which they were delivered.—*The Editors.*

POST-OPERATIVE EMESIS

By J. C. BRADY, M.D., BUFFALO, N. Y.

I. Incidence

Of all the post-operative complications the most frequent and most constant is vomiting. Comparatively few cases, no matter what the operative procedure or anesthetic employed, recover without a period of nausea or vomiting. The causes in order of importance are briefly five:

1. Anesthetic.
2. Anesthetist.
3. Local irritation and length of operation.
4. Patient's general condition.
5. Tendency of certain individuals toward vomiting.

1. Of the anesthetics, ether is notorious, gas oxygen with ether next in order, gas oxygen with morphine and scopolamin following, and ethylene, local and spinal bringing up the rear.

Just a word about spinal anesthesia. From a list of about 750 cases done at the Sister's Hospital these deductions can be made—i.e., that the period when the anesthetic is taking hold there is a sensation of nausea with an occasional slight emesis of bile, this same phenomena being apt to occur a second time when the patient is being shifted from the table to the cart or bed. Following this, vomiting occurs in possibly less than 10% of cases.

2. The selection of a good anesthetist is half the battle. I am convinced that they frequently save the day for us and assure a quiet, orderly convalescence when otherwise we might encounter a very stormy recovery sometimes ending disastrously.

3. Local irritation and length of operation, operations on the upper respiratory tract and undue, rough handling of tissues, pulling on omentum and prolonging the operation over two hours are factors to be eliminated in so far as possible.

4. Debilitated and cardiacs, cardiorenals, etc., are very prone to emesis.

5. Children and neurotics will sometimes vomit for days [illegible]

II. Treatment

Falls under two headings—Prophylactic and Treatment proper.

Under prophylactic treatment:

1. The wise choice of anesthetic and anesthetist

2. The debilitated and cardiacs, etc., should be put in the best possible condition. If there is any question a transfusion is probably the best procedure.

3. In operations on the upper respiratory tract we should use sharp dissection with gentle handling.

4. In neurotic individuals we should see to it that the surroundings are as nearly ideal as possible; that they be kept quiet; and that they have tactful nursing; plenty of sedatives, etc.

Treatment proper:

A little nausea and occasional vomiting in the first twelve hours are of little moment.

In operations on the upper respiratory tract—plenty of ice to cut down the mucous, astringent sprays with or without a local anesthetic are of value.

Avoidance of too much fluid by mount will often prevent troublesome vomiting but small amounts are rarely contraindicated.

Vomiting that persists after twelve hours, or severe or pernicious vomiting requires early and more or less strenuous efforts. Every surgeon has his pet bag of tricks and the advised procedures are legion. For the sake of brevity I am eliminating complicated cases as, diabetics, high obstruction, acute dilatation of the stomach, paralytic ileus, etc.

The most efficacious procedure, out-ranking all others in the armamentarium, is aspiration of the stomach with or without lavage. Personally I favor the simple aspiration without lavage. This to be repeated as often as indicated. In conjunction with this, sedatives, small amounts of fluid by mouth, hypodermoclysis, proctoclysis, and when protracted or alarming, hypertonic saline with glucose intravenously by the slow gravity method.

Other adjuncts of questional value are small amounts of soda in water as a natural lavage.

[illegible]cked ice, gastric sedative powder,

cerium oxalate, bismuth, magnesium, a few drops of chloroform in water, anesthesin, etc., ad infinitum.

For about five years I have been using the duodenal tube, practising aspiration with a bulb syringe, and allowing more liberal amounts of fluid by mouth. The tube is left in attached to the cheek or over the ear and then to a bottle or allowed to hang over a basin beside the bed. This, of course, is backed up by the usual adjuncts of proctoclysis and intravenous saline and glucose if necessary. The procedure is simple and eliminates frequent distressing passing of the stomach tube. It is not uncomfortable and can be retained for days and the intake and loss of fluids readily estimated. I have used it several times on children between the ages of 4 and 5 years and, save for the necessity of splinting the arms for the first few hours to prevent them from dislodging the tube, have found that they readily become accustomed to it.

POST-OPERATIVE PAIN

By J. Y. COHEN, M.D., BUFFALO, N. Y.

Memory for pain is, fortunately, short. In preventing post-operative pain the procedure should be started pre-operatively. One of the things to be done is to give the so-called clinic hypo. It brings quietness of mind and makes the pre-operative state a vague blur instead of a hideous nightmare. In the operating room the operative procedure is very important. Gentleness in handling, lack of mauling, tends to make much less post-operative pain. Also proper suturing is important. Following the operation the proper placing of dressings, especially if the case is a drainage case, makes the patient more comfortable afterward. If, instead of the present wide adhesive strapping which is generally put on much too tightly so that the least distension causes considerable pressure, we went back to the old style many-tailed binders with pins, the patient would be much more comfortable as these could be easily adjusted.

Patient should not be rushed down to his room. He should be placed in bed gently. Position in bed is very important. Patient should be placed so that there is least tension on sutures. Other important points are giving of fluids; quietness; absence of relatives.

On relief from pain Bartlett of Mayo's says "patients should be given morphine." This should be continued for the first 24 to 48 hours when pain is definitely from operation and should be given in doses of at least 1/4 grain and repeated frequently enough to keep the patient perfectly comfortable unless contraindicated or the respirations go below 12. After 48 hours the pain should be controlled by things like luminal. In regard to stimulants they should be given gently. Painful spots following the giving the hypos may result.

Fluids: most men are using the drip method instead of the continuous drip which may become painful. Sometimes 100 to 200 cc. should be given and repeated at frequent intervals.

Difficulty in urination is the cause of much pain. Catheterizing of patient should be done not more than every 12 to 18 hours. After 24 to 48 hours the pain that develops is usually something separate from operation. Surgeon should examine bandage, drains, etc. If, 48 or more hours post-operative, there develops pain which is situated at some distant site it is indicative of something of more severe nature and the cause of this pain should be carefully investigated.

These are the most common causes of post-operative pain: Hemorrhage or infection in the wound; distension of bladder; poor application of dressing; neuritis and backache, postural or toxic; phlebitis and pulmonary embolus.

POST-OPERATIVE THIRST

By ALFRED H. NOEHREN, M.D., BUFFALO, N. Y.

Emphasize four principles:

1. It is much easier to give fluids before operation than after. We should see that patient has a glass of water every hour before operation until two hours before operation, unless it is a stomach case, so that the patient goes into operation with plenty of fluid. Stomach or dehydrated case should be given hypodermoclysis.

2. After operation: start fluids at once. Do not wait. Give water by mouth when patient becomes conscious. Even if he vomits it is usually all right, for it washes out his stomach. If the vomiting persists, or if the case is dehydrated, it should be given by rectum, by Murphy drip or continuously by a tube, or hypodermoclysis: In severe cases hypodermoclysis can be continuous, given slowly. Another method is to give it intravenously. Personally, I am afraid of intravenous medication. Blood transfusion: difficult technique, difficulty in getting donor, matching bloods; sometimes doing patient more harm than good.

Usually use other methods. In case of hemorrhage the surgeon must use transfusion of course. Fluids dilute the toxins, stimulate the excretory organs.

3. Keep the tongue moist; the tongue is the best indication of patient's need for fluids.

4. Best treatment of thirst is prevention. Fluid before, fluid after operation, skillful anesthesia, careful asepsis to prevent infection, and gentle handling of tissues.

POST-OPERATIVE TYMPANITES

By A. W. HEINGERER, M.D., BUFFALO, N. Y.

Tympanites or flatulence takes second place to no other condition following an abdominal operation in disturbing and annoying the patient and taxing the ingenuity of the surgeon.

The condition is referred to with but little attention in our textbooks, as, for example:

Moynihan: "Abdominal Operation"—"If flatus cannot pass easily, 1 tablespoon of turpentine is added to the enema," etc.

Johnson: "Operative Therapeusis"—"Post-operative distention of the intestines is a frequent complication, and is very annoying to most patients. Repeated enemata, occasionally with oxgall and peppermint, relieve this condition as a rule. On the third day the patient receives a cathartic, and thereafter there should be no disturbances on the part of the intestinal tract."

When a patient becomes distended, following an abdominal operation, and complains of varying amount of pain, we are dealing with a condition which may be simple or extremely serious. We are confronted with the necessity of deciding whether the tympanites is caused by

Actual Obstruction:

1. Mechanical adhesions, impaction, etc.
2. Adynamic—paralysis of bowels.

Retention of gas:

3. Mesenteric thrombosis.
4. Peritonitis.

Causes:

Poor preparation of patient prior to operation.

Fecal impaction.

Adynamic Ileus—lazy bowel or actually paralized.

Obstruction.

Neglect, or inability of the patient to empty the bowel of feces or gas.

The symptoms of tympanites and flatulence are distention of the abdomen, rumbling (Borborygmus of the bowel), so-called gas pains, and a desire of the patient to relieve himself either of gas or feces. Percussion yields a resonant sound not changed by change in position of the patient.

1. If the patient's condition permits the best treatment is knee-chest position. This will often permit of the expulsion of gas.

2. Use of the rectal tube.

3. Injection of a large amount of milk of asafetida or asafetida by mouth.

4. Hypodermics of eserine salicylate. This is one of the best drugs for tympanites and should be given in large doses 1/50 gr. (normal gr. 1/100). Atrophine sulphate 1/75 to 1/15 may be given when eserine or physostigmine is not obtainable. If the case is one of adynamic ileus large doses of morphine act well and it is surprising how useful morphine is in these cases. The escape of gas is facilitated by the relief of pain and relaxation of anal sphincter.

Feeding of post-operative patient should not be begun until intestines are free from gas.

POST-OPERATIVE FEAR

By JULIUS RICHTER, M.D., BUFFALO, N. Y.

Of all the emotions fear is by far the most prevalent. It is questionable whether it is not intermixed in varying degrees with every other emotion. It might well be, for it is nature's prime requisite for self-preservation. Were there no fear, the instinct of self-preservation would be almost useless and humanity would have long since perished off the earth. Fear, moreover, is the driving force of life for without it, there would be quiescense and no bodily reactions. Man was born into fear in that he was born into a world where most of the energies were set against him. Everyone

of people with whom you come in contact during an hour and I wager that all have fears of one kind or another. The father fears for his son's future, the clerk for his job, the employer for his investments, the girl for her lover's devotion; all have fears and probably rightly so, for as individuals we need difficulties to overcome and fear is a stimulus to that end.

Fear is not only a widespread but a decidedly contagious emotion. In wild life within the herd or pack, the transmission of fear is unusually rapid. Hunters say that it is easier to approach

It is nature's guard

for the many that the most sensitive single animal starts a stampede. Observe the many instances in history of fear starting with a small nucleus of people, eventually encompassing an entire nation, and ending in wholesale bloodshed; of panic stricken crowds trampling each other to death in their headlong effort at escape; and lastly, in a small way, but nevertheless interesting to us the effect upon patients of foolish pessimistic gossip.

Of the various fears the profoundest and most instinctive is the fear of death. It exists irrespective of intelligence or reason. No one is free from it. A man may shake with fear yet stand his ground because he fears to be called a coward Philosophers and poets are ofttimes psychologists by intuition. Thus to quote Rousseau, "He who pretends to face death without fear is a liar." Lord Byron divines the instinctive quality of fear of death in these lines from "Cain:"

"I live. But live to die, and living see nothing to make Death hateful—save an innate clinging—a loathsome and yet invincible instinct of life, which I abhor; as I despise myself, yet cannot overcome, and so I live—"

If, therefore, the fear of death is instinctive, it follows that you cannot argue or reason a person out of it. You can modify, divert, suppress or submerge such an emotion; but it continues to exist as a psychic entity. It is highly probable that the contemplation of an operation—accompanied as it is by the glamour of the hospital, the glittering instruments of pain, the mysterious sleep of anesthesia, invites fear of death much stronger than we as surgeons are willing to believe. It is feasible, also, that directly after an operation an anxiety complex remains which together with a weakened physical condition is equal to the first, for anxiety and worry are chronic fear.

No one who has kept pace with experimental physiology can doubt the delaterious effects of strong emotion—especially fear. In fact it may be safely said that five-sixths of all human ailments, barring infections and accidents, are due to worry and anxiety. Physical effects of strong fear are known to every layman: palor, cold perspiration, rapid cardiac action, nausea, relaxation of the sphincters, trembling, dilatation of the pupils, etc.,—all of which to a physician describe a picture much like surgical shock. It is a moot question whether sudden strong fear or terror of itself can produce death, but there can be no argument as to this possible end where a concomittant marked debility, such as cardiac disease or the unexplained and little understood status lymphaticus, exists. In the lower animals the effect of fear or anger is to so stimulate or inhibit certain organs as best to prepare the animal for flight or combat. This is brought about by what Williams and Hoag in their book, "Our Fear Complexes," term "the glands of fear and anger" —namely, the thyroid and adrenals It would be futile to go into the details here for the literature is rich in original work along this line. One can see from all these views that however well nature may have seen to the mechanism of self-preservation of the animal or primitive man, it leaves quite another picture when this action takes place in a person of modern social environment. The mechanism is the same but the outlet different. Dr. Crile, in his book, "The Origin and Nature of the Emotions," has graphically presented this phase of the subject:

"We fear not in our hearts alone, nor in our brains alone, nor in our viscera alone—fear influences every organ and tissue. Each organ or tissue is stimulated or inhibited according to its use or hindrance in the physical struggle for existence. By this concentrating of all or most of the nerve-muscular mechanism for defense, a greater physical power is developed. Hence it is that under the stimulus of fear animals are able to perform preternatural feats of strength. For the same reason, the exhaustion following fear will be increased as the powerful stimulus of fear drains the cup of nervous energy more completely visible action may result.

"Perhaps the most striking man and animal lies in the gr man has gained over his prim actions. As compared with th organic evolution, man came t real abode and assumed his s nination over the physical wo ago. And now, though sixth s mand of the complicated m when he fears a business m manifest in the terms of th battle in the struggle for ex fear intellectually, he exp he fears with all his org are stimulated or inhibi a battle of credit or pr physical battle with t but one response to the phenomena are physical."

I am ready to [illegible] persons so const[illegible] leaves an indelibl[illegible] lasts throughout [illegible] believe that m[illegible] irritability, sle[illegible] turbances, con[illegible] etc., attributed [illegible] in reality left [illegible] operation. If [illegible] by some spec[illegible] pain and mor[illegible] proach it [illegible]

could be filled with enough opiate, the proper modus would be established. Such a stuporous nonchalance would be the ideal way to spend the whole period from the night before until forty-eight hours after the operation or at least until one could wake to be oneself with no fearful memories of torture. To effect this sort of "Twilight sleep" in a practical way is not so difficult. Enough morphine or pantopon given hypodermatically to keep the patient in a doze with respirations around twelve beginning the night before operation and continued thereafter for forty-eight hours, or longer if desirable, will produce the result. The advantages are:

1. Fear is eliminated.
2. Pain is eliminated.
3. Spread of infection already there or unwarily introduced is prevented.
4. A circulatory stimulant is provided.
5. It produces a grateful patient with no hangover of fear.
6. The burdens of the attendants are lightened.
7. The procedure is not dangerous.

POST-OPERATIVE CONSTIPATION

By D. C. McKENNEY, M.D., BUFFALO, N. Y.

When patient is ill a long time he is often constipated and takes cathartics. As he is usually thoroughly cleaned out before operation and has eaten little or nothing there need be no hurry about moving his bowels following operation. Pain anywhere tends to cause constipation through spasm. In these cases morphine works better than cathartics. Usually there is an insufficient intake of water and often loss by vomiting, so that there is not much moisture in the intestinal tract unless supplied as Dr. Noehren has indicated.

Due to lack of exercise, feces may collect in the lower bowel and cause an impaction. Practically all the difficulty is in the lower part of the colon.

Another cause is that the patient has some painful rectal condition, hemorrhoids, fissure, ulcer, etc. In these cases an application of adrenalin and cocain flakes may be used locally to relieve the patient's pain so that he can defecate. Mineral oil helps also. Milk of magnesia with the oil is also useful to correct the rectal trouble.

Where there is rectal impaction inject every hour, four times, for retention a small amount of warm water and follow an hour later with a large enema of plain water through a male catheter.

In obstruction cases a thing they are now doing is to supply sodium chloride. After relieving the obstruction inject a solution of sodium chloride into the gut, and give it also by mouth. 75 cc. of 15 per cent sodium chloride solution may also be injected intravenously and this will cause a clean-out in about half an hour.

POST-OPERATIVE EMBOLISM

By EARL P. LOTHROP, M.D., BUFFALO, N. Y.

The question of embolism is closely bound up with that of thrombosis and constitutes, as Forgue says, one of the black spots in abdominal surgery. From the recent literature it is obvious that there is a marked increase in the frequency of both thrombosis and embolism. The age incidents vary from 19 upward with the majority of the cases over 40. The site of operation is apparently unimportant and the primary cause of embolism is still as obscure as ever. Deterring reports that since 1923 the number of these cases has tripled. Although the number of primary or really medical emboli has increased, this increase is not in proportion to the number of traumatic or surgical emboli. In the Burger Hospital, thrombosis increased from 2 to 4 per 1,000 in 1919, to 16 per 1,000 in 1927. Parallel with that the number of cases of fatal embolism increased from 1 to 4 per 1,000. Henderson reporting on 63,000 operative cases from the Mayo Clinic states that "8 to 10 per cent of post-operative deaths are due to embolism the incidence being 0.34." Kuhn of the Pathologic Institute of Freiburg, reports that, between the years of 1924 and 1927, fatal embolism increased from 1.3 per cent up to 4 and then 9 per cent, while thrombosis in 1927 was found in every 4th body. This report, of course, included cases of medical thrombosis and embolus, but emphasizes the fact that there had been a large increase. It has been thought that the increased number of primary emboli was due to the better care cardiac cases are now receiving. With modern methods of intravenous medication the life of the cardiac is prolonged beyond the point where they formerly died from decompensation. They are now dying from embolism.

As stated before the real cause of formation of thrombosis and embolism has not been deter-

mined and those factors which have been regarded as active in the past are now looked upon as predisposing causes, such as:

1. Slowing of the blood stream.
2. Injury to the endothelium.
3. Changes in blood.
4. Decreased metabolic activity.
5. Lowered blood pressure.
6. Sepsis.

There is no agreement among investigators as to the relative importance of these factors although in certain clinics one is stressed more than another. The majority agree that slowing of the blood stream is not sufficient but that injury to the endothelium is necessary. Injury to the endothelium is brought about by trauma such as occurs in fracture of the limbs, severe blows upon the abdomen, extension of infection from neighboring wounds or certain types of bacteria in the blood. There seems to be no evidence to prove that intravenous medication has played any part in the production of thrombi and the number of emboli which have occurred following injection of varicose veins is exceedingly small. Changes in the white cells, platelets, blood calcium, fibrinogen, and prothrombin have always been recognized but, like the report of Mark Twain's death or the weather, their importance has either been exaggerated or ignored. However, two bright spots stand out in the literature indicating two definite attempts to solve this problem, one from the chemical, the other from the metabolic standpoint.

Bancroft and his associates report an interesting experiment which is being conducted at the Fifth Avenue Hospital from the standpoint of blood chemistry. Recognizing that there are certain elements in the blood which favor clotting and others which antagonize it, they are attempting to determine in advance whether the patient's antithrombin or prothrombin hold the balance of power and, by a second analysis three or four days later, to record the changes in their relative strength. They have observed in those individuals who live on a high protein diet, a greater tendency to thrombosis and embolism than in those who subsist on a fruit and vegetable diet. They have found that the ordinary method of estimating clotting time is of little value and recommend that the clotting index of the blood be determined according to the following formula: the percentage of prothrombin plus the percentage of fibrinogen is divided by the percentage of antithrombin, this formula giving what is known as the normal clotting index which is 0.5. They are searching for a simple test of one factor in the blood which can be universally used and will give a relatively accurate idea of the clotting index. So far they have been unsuccessful but the whole work is a step in advance and the article referred to is worthy of careful reading.

The other bright spot is at the Mayo Clinic. Walters reports in January 30th issue of "Surg. Gyn. Obs.," the use of thyroid extract post-operative from the third to the tenth day to increase general metabolism. His argument is based on the fact that a post-operative patient doesn't breathe deeply, abdominal muscular action is inhibited and residence in bed leads to inactivity of the muscles of the trunk and limbs. This, he believes, is the most important factor in the formation of thrombi and thyroid is recommended because it increases metabolism. In proof of his claims he reports 4,500 cases so treated with embolus death-rate of 0.09. The part which sepsis plays in thrombosis and embolism is still an open question. Undoubtedly it is a factor and is present in large percentage of cases but it is also true that a goodly number of cases occur in which sepsis cannot be proved so it must be left as a predisposing factor.

When I stated that the etiology of thrombosis had not been determined I overlooked the opinion of a bright young man who recently solved the problem and stated his theory in the following words: "Boshamer is of the opinion that thromboses, post-operative and essential, are the result of a lability of the vasomotor and the autonomic nervous systems, i.e., a parasympathicotonic hypertonia, developing as the result of a sympathetic irritation (surgical injury, cell degeneration) superimposed on an enfeebled circulation with imbalance of the splanchnoperipheral circulation, contraction of veins in the liver, disturbance in the metabolism of proteins in the liver, blood changes, and injury of the intima."

POST-OPERATIVE ILEUS

By JOSEPH BRENNAN, M.D., BUFFALO, N. Y.

ILEUS is a symptom complex of pain, tympanites, vomiting and obstipation. There are two main types seen post-operative: mechanical and paralytic. The mechanical type is ordinarily due to adhesions, bands, etc., but may occasionally be due to tumors, volvulus, intussusception. The paralytic type may be very insidious in onset, and may be easily overlooked in its early stages. It is a fact that when a patient has been operated surgeons are often slow in recognizing ileus.

Both types of ileus show after developing much the same clinical course. The usual case has all four of the symptoms mentioned. If

these are not relieved by enema, stomach washings, duodenal tube and sodium chloride, one should be prepared for further surgery.

Obstruction high up in intestines is rapidly fatal. If not soon relieved by operation the patient rapidly goes into the terminal stage, with rapid pulse, cold clammy perspiration, fecal vomiting, drooling, and dies. Conservative measures should not be persisted in up to the onset of fecal vomiting. Fecal vomiting is not so much a symptom of intestinal obstruction as it is a sign of approaching death. It is then too late for surgery.

There is a similarity of symptoms in patients in terminal stages of ileus and those dying in shock or gas gangrene. The intestines are blocked off, tremendously ballooned, and are just a pool of toxic material. This toxic material has been injected into guinea pigs and dogs by many different workers using much the same technique, but there is a wide diversity of opinion as to the cause of death. It has been claimed that death is due to starvation, dehydration, loss of chlorides, high nitrogen urea in the blood. According to Hayden and Orr, death is due to deficiency of chlorides. Williams gives serum on the theory that the underlying cause is the gas bacillus of Welch. It has also been claimed that the cause is lack of bile going through the intestines, and human bile enemas have been given with some success in this connection. I cannot, then, give the exact cause of death in ileus. It is probably due to absorption of nucleoproteins from the degenerated intestinal lining, in combination with other factors, dehydration, loss of chlorides and alkalosis.

The treatment should be largely one of prevention. Thorough knowledge of the patient beforehand, study of blood chemistry, not too early catharsis, replacement of fluid, return to the normal water balance in the body would do much in the way of prevention. In this connection too, in certain selected cases, it is well to perform an ileostomy as part of the original surgical work.

Gentle handling of tissues is important in preventing pain and also in preventing ileus. Rough handling of tissues is secondary in importance only to peritonitis in the formation of multiple fine adhesions. These fine adhesions can easily cause ileus of mechanical type, in fact they do cause 75% in the opinion of one observer.

The treatment of ileus will vary somewhat with the type, whether mechanical or paralytic. In the mechanical, removal of bands, adhesions, etc., is often sufficient, if done early. If late, the cause must be removed and case treated as paralytic ileus. Enterostomy is done, and because of greater toxicity of the contents of the jejunum, jejunostomy serves best to relieve the toxicity and depression. Intestinal contents are replaced with sodium chloride solution, with 5% sodium chloride in the veins, and 3% in large quantities under the skin.

Some surgeons have advocated stripping the entire small intestinal tract over a glass tube to thoroughly empty it. This seems a radical procedure, and must be determined by the condition of the patient.

The use of spinal anæsthesia in paralytic ileus has been shown to be of value both in differential diagnosis and treatment.

POST-OPERATIVE PERITONITIS

By MARSHALL CLINTON, M.D., BUFFALO, N. Y.

The commonest cause of death after an abdominal operation is peritonitis. To properly understand what the abdominal structures do in peritonitis when they follow the protective impulses, it is necessary to have a proper understanding of the philosophy of the treatment of this complication.

The physiology of the peritoneal cavity is such that when there is insult by injury from a foreign body or bacteria, the reaction is distension. This distension is comparable to the loss of function following injury to muscular tissue.

Peritonitis spreads by a mechanical extension due to peristaltic waves, by direct extension and through the lymphatic system. In the treatment of peritonitis, we cannot control direct extension nor can we control extension through the lymphatic vessels, but we can modify the spread of a peritonitis by controlling peristalsis. The mortality rate of an early spreading peritonitis has been reduced at least sixty per cent by following out the general treatment outlined by Dr. Ochsner of Chicago. He showed how a spreading peritonitis generally could be controlled by giving the patient large doses of tincture of opium per rectum, by keeping the stomach completely empty, by using the stethoscope on the abdomen to determine if any peristalsis is occurring, and by keeping the patient's respiration down to at least ten to twelve per minute. I think we sometimes forget that anything in the stomach will start a peristaltic wave that spreads throughout the entire intestinal tract and as this is one of the most harmful things that can happen to a patient with a spreading peritonitis, the stomach should be kept completely empty and fluids supplied per rectum and subcutaneously.

In our own experience we have seen this change in treatment of a peritonitis over a period of thirty years at which time the greater majority of patients died of this complaint. Today, we find that our mortality rate in cases of spreading peritonitis is less than six per cent.

POST-OPERATIVE HEMORRHAGE

By WALTER L. MACHEMER, M.D., BUFFALO, N. Y.

When hemorrhage does exist, there can be only one treatment—that being to stop the bleeding. This, as you know, may be accomplished by several different methods. Little need be said of the signs and symptoms of hemorrhage, also the treatment of the effects of hemorrhage shall receive only a passing comment.

Transfusion, which very often is put off until too late, should be used early. Instillation of fluids, such as glucose and saline solutions can be used intravenously and subcutaneously, orally and rectally. In the use of glucose subcutaneously, a five per cent solution can be used and is a method commonly used at the Children's Hospital, and also normal saline solution intraperitoneally, but in cases of intra-abdominal hemorrhage, the last method would be contra-indicated.

We shall deal with the prevention of hemorrhage rather than with the treatment. I would make the following suggestions: that any vessel which has a name should receive the respect of the surgeon; and when such vessels are encountered they should be tied as vessels rather than part of a piece of tissue. In other words, vessels, such as the renal, splenic, cystic, etc, should be identified as such before ligated. All important ligatures should be anchored.

Promiscuous tearing of adhesions may sometimes result in a continuous large hemorrhage.

In dealing with cases of increased abdominal tension, the sudden release of such pressure may permit a fatal hemorrhage within the abdomen. The manhandling of an inoperative lesion, such as carcinoma, may produce an uncontrollable ooze which may be equivalent to a real hemorrhage.

In making an anastomosis, the use of clamps may sometimes produce hemostasis only during the operation and if the same are released, a hemorrhage may occur. The mucous membranes are very vascular, and for that reason, it has been our practice to suture the same with a locked stitch or stitch tie suture. In a gastroenterostomy, we have not used clamps for many years and find that they are quite unnecessary in controlling the escape of gastrointestinal contents and we feel that our hemostasis is much more perfect, especially using the stitch tie suture under these circumstances. As this method of anastomosis is so complete, it has not been necessary to use any drainage.

POST-OPERATIVE SECONDARY INFECTIONS

By ALFRED H. CLARK, M.D., BUFFALO, N. Y.

Secondary infections which complicate or prevent recovery from abdominal operations may be 1. Those caused by organisms already at site of operation found at or just before time of operation, as in

A. General or Localized Peritonitis.
B. Multiple Abscesses from Infected Emboli in Lungs, Liver, Spleen, Kidneys, etc.
C. Pylephlebitis.
D. Single Abscess of the Liver.
E. Subdiaphragmatic Abscess.
F. Phlebitis.
G. Abscess of Lung.
H. Empyema.
I. Pneumonia.
J. Endocarditis.
K. Arthritis.
L. Pyelitis.
M. Perinephritic Abscess.
N. Parotitis.

The above named infective complications may come from:

Appendicitis; Ruptured Viscus; Cholecystitis; Diverticulitis; Pancreatitis; Perinephritic Abscess; Salpingitis; Parametritis; Metritis; Endometritis; Oophoritis.

2. Those arising from infections elsewhere in the body, as in the Teeth; Tonsils; Sinuses; Chronic Gall-bladder; Bacilluria from infections anywhere along the urinary tract, or from the upper air passages.

These include:

A. Pneumonia.
B. Endocarditis.
C. Arthritis.
D. Parotitis.
E. Epididymitis.

Parotitis can be metastatic in origin or from organisms ascending through the duct from the mouth. It is said to occur more frequently in pelvic operations than those in the general abdomen. More than half of the reported cases go on to suppuration. Judging from the few that I have seen this would seem to be an exaggeration —probably due to the fact that the suppurative ones are more dramatic and are more apt to be reported.

3. The third group of infective conditions are

those which are introduced from without at the time of operation, for example: Wound infection; infected suture material; spray from the operator's mouth; dust; sweat; careless sterilization; or colon bacillus infections in operations upon the bowl or in accidental injury to the bowel.

Urethritis, cystitis; pyelitis may be due to infection during catheterization.

"Health News" of February 17, 1930, quotes from "Municipal Sanitation" (January, 1930), on the danger of having the water intake of sterilizers below the water level in the sterilizer. They reported a case in which the pressure in the water system in the building was reduced enough so that water contaminated by soiled instruments in the sterilizer was sucked into the general water system thus completely contaminating it. They reported, also, a case where the still for distilled water was connected directly with the sewage and in which the operator forgot to close the tap after blowing the steam out of the still. Then when the still cooled, sewage was sucked directly in and mixed with the sterile water so when they thought they were using distilled water they were using about one part of distilled water to twenty of sewage.

POST-OPERATIVE ABDOMINAL AUSCULTATION

By JAMES E. KING, M.D., BUFFALO, N. Y.

A large number of abdominal operations are associated with some postoperative disturbance of intestinal peristalsis, either as a result of perverted nerve impulses or as a direct effect of a complication. To him who becomes familiar with the postoperative behavior of the intestines as revealed by auscultation, the stethoscope will contribute much to a better understanding of these clinical conditions, and it will sometimes render valuable aid in the early diagnosis of certain postoperative complications.

The postoperative disturbed nerve impulses may be regarded as producing in the intestinal tract three results: inhibition, overstimulation, and reverse peristalsis. The question as to whether these states are produced reflexly, as a result of the abdominal incision or whether they follow manipulation of the intestines and originate in the sympathetic system will not be discussed.

The course of events in the majority of laparotomies is as follows: For a variable period auscultation shows a much diminished peristalsis. Peristalsis increases during the next twenty-four to forty-eight hours, and the pain associated with it bears a relation to the severity of the contractions. The first stage may be regarded as the stage of inhibition, the second as one of spastic contraction. The spastic stage following the stage of inhibition produces the pain we designate as "gas pains." The term is appealing, although not entirely accurate, as frequently severe pain of this stage is not associated with distension. The stethoscope during this stage shows marked peristalsis of the sudden forceful type.

Perhaps the most typical illustration of the use of the stethoscope in peritonitis is found in the ruptured appendiceal abscess. Almost directly there is a marked decrease in intestinal movements. By the time the patient is seen by the surgeon, peristalsis has ceased. Our house surgeons like to characterize this as the "graveyard belly," a term which unfortunately may have a double significance. This state of affairs persists for three days, four days, or perhaps a week, and then one day a gentle sound is heard and after an interval another, which relieves uncertainty. The stethoscope under these circumstances is a great comfort, and makes it possible to take a firm stand on diagnosis and treatment, and helps in determining the prognosis.

Postoperative obstruction of the bowel is dreaded by every surgeon. Its early recognition is essential for successful treatment. The diagnostic criteria furnished by the average textbook are often those of an advanced stage. Vomiting and cramp-like pain are the two clinical indications of the greatest importance. Postoperative vomiting that persists after twenty-four hours, or vomiting that begins two or three days after operation, calls for careful analysis in its relation to the general clinical picture, together with the evidence obtained by abdominal auscultation. The stethoscope demonstrates active peristalsis, and one is justified in expecting, if the case is not one of obstruction, that an enema will bring gas. If repeated effort in this direction fails and if at the same time there is increasingly violent peristalsis, a diagnosis of obstruction is justified.

Perhaps one of the greatest values of the stethoscope is in the early differentiation between obstruction and peritonitis. I have never known it to lead one astray if the evidence obtained by auscultation has been carefully considered in connection with the clinical evidence.

PRESENT-DAY METHOD FOR TESTING THE HEARING AMONG SCHOOL CHILDREN*

By EMILY A. PRATT, M.D., ALBANY, N.Y.

From the Medical Inspection Bureau, State Department of Education, Albany, New York.

THE early literature gives nothing on tests of hearing.

It was not until 1821 that we note actual mention of a device for testing hearing. This is by the great otologist, Itard of France.

The transmission of sounds through the cranial bones in diagnosis of aural diseases was first studied by Johann C. A. Lucae, (1870). Rothenburg, in 1896, introduced new tests for audition in deafmutism and in unilateral deafness in 1897.

Various methods of testing hearing were discussed by T. M. Clarke, M. B.[1] For example, he says, "The human voice has long been used for such tests, and inasmuch as the ability to hear and understand speech is the criterion par excellence of hearing ability, it is unfortunate that its disadvantages outweigh its advantages."

The voice cannot be standardized.

The tuning fork is a dependable tool so far as *constancy* of *pitch* is concerned. This is for the aurist only and not the school authorities.

The ability to hear a watch, so-called watch tick test, is convenient. The results are on the rational hearing distance basis. This method has been the most satisfactory one we have had for testing groups of school children.

A considerable drawback to spoken or whispered speech is found in the fact that it is impossible to employ a uniformly strong voice on different days. Fatigue plays an important part. Even if we succeed by continued practice in training our voice and speech apparatus to a uniformly strong pronunciation the clearness of our voice will on many days be temporarily altered by trifling changes in the larynx and the ligaments of the glottis. In loud speech the volume of the sound of the vowels and of the consonants makes its use unsuitable.

"Politzer[2] hoped for the production of an instrument which would give a standard intensity of sound. The difficulties of production have apparently been too great, for acoumeters are encountered which vary widely in loudness."

"The audiometer does away with the uncertain loudness of the sound used in quantitative estimation of the acuity of hearing and gives us the ability to plot an audiogram that will mean as much to some one else as it does to the man who made it. *Perhaps* it will enable us to discern evidences of beginning deafness, whereas, when deafness is established, it is all *too often hopeless.*"[3]

So we come to the year 1925 and note an article by Dana Drury, M. D., of Boston which occurs in a number of the *Laryngoscope*. The title is "The Tests of 500 Average Ears."

These tests were made with the phono-audiometer, developed by the Western Electric Company under the direction of their physicist, Harvey Fletcher, Ph. D., together with the cooperation of physicians such as Dr. Fowler, Dr. Hays, Dr. Newhart and others and stimulated and cooperated by the American League for the Hard of Hearing.

We now have a device that detects incipient disease among school children by means of measuring the hearing in units of hearing loss. When the loss of hearing is found by the school health service, parents are notified that they may procure medical advice.

This device detects from five to ten percent, whereas by the obsolete methods, the voice and even the watch tick test, only one percent was found.

We therefore have an aid to diagnosis, to research and in determining the fitness of an applicant for the type of work for which he is making application; and to education. It estimates the degree of hearing of school children that "special" education may be provided for those who need it. (This special education is in the form of speech or lip reading.)

The phono-audiometer, as the name implies, is a device for measuring the degree of hearing loss in vibration units by means of an electromagnetic phonograph that revolves a special record. A voice repeats four columns of numbers for each ear, the numbers becoming fainter as the end of the column approaches. The machine is calibrated on exact mathematical and electrical measurement so that there is no difficulty about unification of a standard.

It produces speech electrically. It has been calibrated after innumerable tests to take care of the average outside noises and to be adapted for use in the average schoolroom.

It is economical of time and money. The device has 40 earphones which are attached to the phonograph, thereby making it possible to test an entire class at a time. All grades from the third up can be tested by this method. With time and patience the second grade can often be tested. Each child is provided with a prepared sheet of paper, on which he records the columns of figures he hear. If he hears only the figures at the top of the col-

*Read at the meeting of New York State Women's Medical Society, at Utica, N. Y., June, 1929.

umn his hearing loss is greater than when he is able to hear and record the entire column. All papers are corrected by means of selecting the better column for each ear and comparing it with a master sheet. All children found defective on the first test are given a second test to eliminate the element of fear, failure to cooperate, slowness of comprehension and so on, in order that the children who really do not hear may be noted.

The units of hearing loss are noted in columns on the record sheet. These units commence at 30 and decrease to 0 and —3. The numbers spoken decrease in regular steps, 3 *SU from a point louder than one with normal hearing* could hear easily, to a point at which only one with the best of hearing could interpret the numbers. Zero indicates normal hearing as noted by no loss of vibration units. Minus three indicates acute hearing.

The record of this test is in units of hearing loss. Everything under 6 may be considered normal. A loss of 6 units should be considered as questionable. A loss of 9 SU or more means defective hearing. The greater the loss the more serious is the defect. *All children found defective should be referred for otological examination.*

The New York State Medical Inspection Law (Laws of 1913, Chapter 627) provides that medical inspectors or principals and teachers in charge of public schools shall make eye and ear tests of the pupils in such schools, at least once in each school year. This is true of other states. We now have a means of more adequately carrying out the law. Many school boards throughout the United States use this phono-audiometer. The American Federation of Leagues for the Hard of Hearing have honored all cities which use this device and their local city clinics, and who provide Speech Reading for those who are deafened, designating them as "Three Point" cities. Rochester of New York State is one so listed.

Exclusive of Rochester, Buffalo and New York City the following statistics have been gathered in New York State during the school year 1928-1929 in an effort to establish the universal use of the phono-audiometer throughout the state as well as determining the incidence of hearing loss among school children.

The first survey was made in Poughkeepsie in 1926 with the result that 9½% out of 600 children were found defective.

Four hundred and thirty tests were next made in Schenectady with 5% found defective.

Later in Nyack 892 grade children were tested with 9.6% defective, 80% of whom had otological defect, consisting of adenoids and tonsils; impacted cerumen; otitis media, chronic and acute; chronic catarrh and nasal obstruction. Nine percent, or all but a very few of those found defective were recommended for lip reading instruction. Corrections were made on only 46%, or less than one half of the 80% of otological defects found.

In Hudson a larger group of children was tested and all defective given an otological examination. This same group was tested the following year and given a third test and a second otological examination.

The following points were noted:

1. Number of children tested.
2. Number found defective on first test.
3. Retest of above.
4. Number found defective on retest.
5. Number of above with otological defect.
6. Number of above retarded one or more school terms.
7. Number recommended for lip reading.
8. Number recommended for a deaf school.

The survey started with 1097 tests which included all grades and the high school.

The high school pupils pass out of the school system before much can be done in the way of follow-up work and special education. (It often takes from five to ten years to bring about some new phase of health work owing to many factors. One is that physicians doing part time school health inspections are too busy with their general practice to familiarize themselves with modern health measures and so fail to present the need for these newer methods to their Boards of Education.)

Four hundred and eighty-two *grade school children* were selected for the final study.

Out of this number, 398 or 82% had normal hearing.

68 or 14 plus percent had defective hearing (a hearing loss of 9 or more units.)

16 or 3 plus percent *were borderline* (6 *hearing loss units.*)

Of the 68 or 14%, 56 or 82 plus percent had an otological defect.

Of the 16 or 3 plus percent, 11 or 5 plus percent had an otological defect.

There were 67 children out of 482 with an otological defect.

There were 56 children with definite hearing loss.

The fact which I wish to bring out is that 14% of those tested had a definite hearing loss. They were handicapped by poor hearing.

82% of the 14% had an otological defect and in addition 3% of the borderline cases making a total of 84 with otological defect. If the otological defect could be corrected, there would be a chance for improved hearing in the 82% and normal hearing in the 3%. For example, 18% had impacted cerumen. If this were removed, hearing might be normal in this group which is only a fraction of the

number found to have a hearing loss The same would be true, to a certain extent, of diseased tonsils and adenoid tissue, acute otitis media and chronic catarrh to say nothing of the sinus infections A certain proportion of this 14% will remain deafened They require special education in *Speech Reading* The remainder need *prevention* Dr Franklin Bock, of Rochester proves this point each school year See also author's "Report on Preventive Work Being Done in One of the Schools for the Deaf" which appeared in the September number of the *American Annals of the Deaf*, 1928

The number of children with pedagogical retardation and defective hearing estimated after the third test was 59% That is to say that of those found with defective hearing, 59% had been kept back one or more grades (*There were 29 children who were repeaters* out of the 49 with defective hearing)

This seems like a large number The statement has been made that 3% of those children who are retarded pedigogically are so retarded because of defective hearing

The above statistics should of course be accompanied by a report of intelligence quotients It points out, however, the importance of detecting defective hearing among school children that a child with normal intelligence shall not be listed as mentally deficient or be considered a repeater and so an added expense to the School System

A recent report from one of the larger cities substantiates the Hudson findings of 59% of the children with defective hearing being pedagogically retarded

It is my belief that the percentage of those children pedagogically retarded who are found to have a hearing defect is greater than 3%, thus emphasizing the importance of early testing In this way the children will not lose valuable time and be classified as "stupid"

The phono audiometer has been used in 15 school systems in New York State during this school year (1928 1929) Some of these places were cities, some villages and some sections of rural districts

18,198 school children were tested Out of this number 1,169 were found defective This is 6 4% of the total tested

As previously mentioned only one per cent of all school children in New York State was found to have defective hearing as estimated by means of the now obsolete methods (Article by the author on 'Lip Reading—Its Need' presented before the American Federation of Leagues for the Hard of Hearing at their annual meeting 1927)

We can safely say that from five to ten per cent of school children have a definite hearing loss This is sufficient to recommend that the phono audiometer be used as an *accurate method* of estimating hearing loss

Children so handicapped should not pass into life 'through carelessness and inattention and from neglecting premonitory symptoms' as pointed out nearly one hundred years ago by John Harrison Curtis aurist to King William IV in 1831

In so many respects we have passed far beyond that period of civilization that we have *no right to persist in using obsolete* methods There are those who believe that legislation throughout the United States should be enacted that the phono audiometer shall be universally adopted Certainly scientific testing of school children should become universal Perhaps legislation will not be necessary

LEUKOSARCOMA WITH MEDIASTINAL TUMOR

By BURTON L ZOHMAN, M D, BROOKLYN, N Y

From the Service of Dr Henry Joachim and Dr Joseph Rosenthal Department of Medicine United Israel Zion Hospital Brooklyn N Y

LUKEMIAS are occasionally observed which, both clinically and micro pathologically, show great similarity to the malignant neoplasms, especially to the sarcomas, by extensive and sometimes multiple growths Hematologically, cases of leukosarcoma are characterized by a predominance of large mononuclear, non-granular leucocytes which have a large, round or oval notched nucleus, which is hyperchromatic, possesses a thread network and several vacuolar structures within The protoplasm of these cells is scanty Anatomically, there is an atypical proliferation of the lymphatic apparatus closely resembling lymphosarcoma in *contradistinction to the actual hyperplasia* of the lymphatic organs as it occurs in lymphatic leukemia The tumors may be found in the prostate, breast, tissues of the orbit, the retroperitoneal space or in the mediastinum The primary site of our tumor was in the mediastinum

Case Report The patient, a white male, aged forty-eight years, was admitted to the United Israel-Zion Hospital on October' 2, 1928 He was apparently in good health until four weeks

before admission when he fainted while at work. About three weeks prior he began to cough slightly and would experience occasional sharp pains in the left lower chest. He remained at work until four days before admission when he had a sudden sharp attack of pain in the left chest with difficulty in breathing and a dry hacking cough. Since the onset of the patient's illness, there were marked night sweats, a poor appetite, weakness and a loss of ten pounds in weight.

On physical examination the patient was orthopnœic; the face and tongue were cyanosed. There were shotty glands in both the anterior and posterior triangles of the neck. The chest was of the emphysematous type with bulging of the left lower axilla. There was dullness with diminished tactile fremitus posteriorly beginning at the spine of the scapula down to the level of the angle on the left side, becoming flat at the extreme base. The entire left axilla was flat to percussion and the breath sounds were markedly diminished. Anteriorly, there was flatness on the same side beginning with the 3rd interspace downward and extending over to the mid sternum. The right border of the heart extended four and one-half centimeters from the midsternal line in the fourth space. There were a few enlarged inguinal glands and some prominence of the lower abdominal veins. Rectal examination was negative.

Following *x*-ray examination which disclosed a considerable left pleural effusion with the heart and mediastinal contents markedly displaced to the right, a thoracocentesis was done and 2,100 c.c. of bloody fluid were removed. Examination of fluid showed a predominance of lymphocytes, was negative on culture and for tubercle bacillus. Blood study on the following day revealed 4,700,000 red blood cells, 85% hemoglobin, 23,500 white blood cells with a differential count of 30% polys and 70% large mononuclears. At this time, a clinical diagnosis of leukosarcoma was made with the primary tumor invading the mediastinum. On the 5th of October, right and left axillary glands were felt. The trachea was considered fixed and the larynx was negative. *x*-ray showed a mediastinum which was tremendously widened, the external border of which presented a more or less scalloped appearance. The left chest showed evidence of being half filled with fluid which, when removed, was amber colored, negative on culture and for tubercle, and on section showed the same type of cell which was so characteristic in the blood. A biopsy of a cervical gland failed to reveal anything significant.

On the 8th, the submaxillary, supraclavicular and axillary glands were palpable, more marked on the left. A blood study showed 4,800,000 red cells, 85% hemoglobin, 220,000 platelets, 36,000 white cells with 16% polys and 69% large mononuclears, 3% atypical cells and 12% smudges. The oxidase reaction was negative. On the 10th, 1,500 c.c. of similar fluid were removed. On the 12th, the vessels over the anterior chest wall appeared prominent. The patient was given mediastinal irradiation. On the 15th, the erythrocytes numbered 5,500,000, the hemoglobin 80%, platelets 100,000, white blood cells 25,000 with 38% polys, 53% large mononuclears, 2% atypical cells and 7% unclassified. On the 18th, the liver was felt one and one-half fingers' breadth below the costal edge. On the 25th the red blood count was 5,000,000, hemoglobin 85%, platelets 90,000, white blood cells 23,600 with 40% polys, 55% large mononuclears and 1% unclassified. One per cent normoblasts were also present. On the 27th, *x*-ray irradiation was again given. On the 31st, the patient was very dyspnœic; the liver was felt 4 fingers' breadth below the free border, the spleen was not enlarged. The hands and face were cyanosed. The patient expired at 4 P.M. on the same day.

Repeated urine examinations were negative as well as Wassermann and sputum examination for tubercle.

Autopsy Findings (Dr. Max Goldzieher). The main tumor extends all over the anterior mediastinum. It is adherent anteriorly to the sternum and cannot be separated from the anterior surface of the right lung. It also encroaches upon the anterior surface of the pericardium. Posteriorly, it is in connection with several large lymph nodes which are fused together and surround the bifurcation of the trachea. The tumor tissue is white in color, mainly medullary and fairly soft in consistency, while other areas are more fibrous and firm. The lymph nodes which are partly fused with the main tumor, show anthracotic mottling.

Microscopically, the tumor in the anterior mediastinum consists of very cellular areas alternating with areas containing large foci of fibrous character. The cellular areas reveal a very fine reticular stroma in which the tumor cells are imbedded. These, although they are rather irregular, varying as to the size and shape of their nuclei, resemble lymphocytes. Their cytoplasm is scanty like that of a lymphocyte, however, the size of the nucleus exceeds that of a lymphocyte two or three times. Sections from the liver show extensive infiltration with tumor cells particularly in the periportal connective tissue. The hepatic sinuses also contain isolated cells of this type. The cells infiltrating the periportal connective tissue yield a negative oxydase reaction. The kidneys show the same type of infiltration. The spleen shows rather small follicles surrounded by hyperemic pulp. There are many of the large cells, comparable to those of the tumor, scattered all over the pulp and particularly

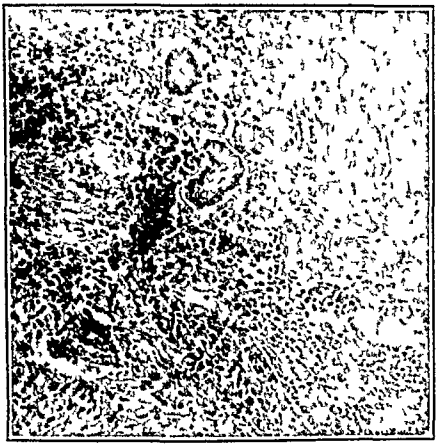

FIGURE 1

Section of kidney showing area infiltrated with large cells with intensely staining chromatin nuclei of type found in primary tumor mass
Zeiss—objective 8—Ocular 10

FIGURE 2

Section of liver showing interlobular space infiltrated with cells of same type as found in the original tumor mass
Zeiss—objective 8—Ocular 10

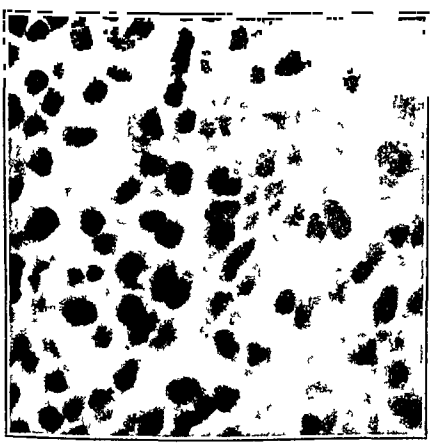

FIGURE 3

Section of tumor from mediastinum showing cells with very intensely staining nuclei of various shapes of similar type as found in blood
Zeiss—objective D—Ocular 10

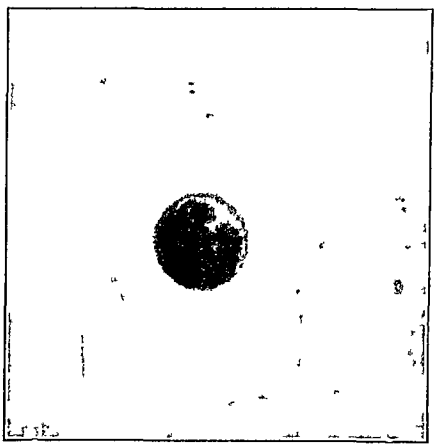

FIGURE 4

Blood smear showing typical white cell with intensely staining notched nucleus and small rim of cytoplasm
Leitz oil immersion—Ocular VI

in the hyperemic areas of the pulp Large quantities of eosinophilic leucocytes and myelocytes are also conspicuous A large number of oxydase positive cells are irregularly scattered over the pulp They surround the follicles in ring form There are practically no oxydase positive cells in the follicles

Comment A case of an irregular type of blood dyscrasia is presented It resembles closely the other types occasionally reported in the literature as leukosarcoma It is likewise characterized by a large tumor mass and a leukemic blood picture wherein the cells are similar to those in the tumor

THE CLINICAL SIGNIFICANCE OF ABDOMINAL PAIN IN CHILDREN*

By EDWARD J. WYNKOOP, M.D., SYRACUSE, N. Y.

THE advent of acute abdominal pain should always bring to the mind of the attending physician the question as to whether he is dealing with a medical or a surgical problem.

The occurrence of acute abdominal pain whether developing in the course of some acute illness or being the first sign of a surgical disturbance in the sick child, is a warning that should not go unheeded and should put us eternally on our guard.

Failure to properly interpret the symptoms may cause serious delay in arriving at a prompt diagnosis and postpone proper treatment.

Should the case prove to be medical in type, delay is not always so important but on the other hand, if the abdominal pain is a symptom of some surgical condition, delay may mean serious consequences, especially, in the young. The statement has been made "that it requires considerable judgment to give abdominal pain in the child its proper interpretation."

Whether the pain is superficial and muscular, or deep due to some infection of the visceral contents of the abdomen, should be determined accurately and with dispatch.

Pain of this type accompanies many conditions in childhood.

Intestinal Colic, Appendicitis, Pneumonia, Acute Peritonitis, Intussusception, Pyelitis, Strangular Hernia, Over-distended Bladder, Intestinal Parasites, Lead Colic, Rheumatic Fever, Movable Kidney, Acute Gastric Intestinal Indigestion, are some of the causes of abdominal pain.

The pain that is sometimes noted early in an attack of Catarrhal Jaundice should be mentioned. In the writer's experience, abdominal pain coming on in the course of what has seemed to be an ordinary Catarrhal Jaundice has proved in two instances to be the forerunner of those serious symptoms which turn out to be Icterus Gravis.

There probably is no disease that attacks the young which shows such a variety of symptoms, in its wanderings and vagaries, as the Pneumonias of Infancy and Childhood. Every hospital holds records of a good many cases sent in for surgical treatment with the diagnosis of an acute abdomen, only to find the pain is the result of disease in some other part of the body.

What physician has not been tried to the utmost in caring for a case that unquestionably showed atypical symptoms of respiratory infection and yet the abdominal pain has been so severe, the surgeon has been called in to help shoulder the responsibility. As one gets older in the field of medical practice, certain rules are many times formulated in one's mind and frequently symptoms are grouped together to prove the infallible rules of diagnosis. Then the unusual and unexpected happens, and we find while we may have been long in the fight against disease, there remains much to be learned for something new is forever showing up in the field of clinical medicine.

The suddenly stricken child, acutely sick with or without a chill, profoundly toxic, high fever, rapid respiration and pulse, severe abdominal pain, vomiting, expiratory grunt, with or without cough, the symptoms may point pretty definitely to respiratory infection but a search for any evidence of disease in the lungs, may for several days be futile.

Add to the picture severe abdominal distention; not only is the diagnosis rendered more difficult but the prognosis certainly is definitely worse. In the typical cases of Pneumonia with cough, fever, rapid respiration and pulse, abdominal pain may also be severe but early signs of disease in the lungs are easily recognized.

In these cases of unquestioned respiratory infection in which an accurate finding in the lungs is not at first possible, the careful analysis of the history together with a minute and thorough physical examination will reveal as a rule signs that point to the true cause of the disease.

Our hurry in skimming over a poor history added to insufficient time in a superficial examination, will many times cause us to overlook the warning signals.

The development of laboratory facilities, including blood count as well as *x*-ray examinations, make us lean altogether too much on these great aids in diagnosis.

We sometimes forget that clinical symptoms are just as valuable today as in the early centuries and our diagnostic ability ought to be sharpened rather than dulled by the progress made in medical science. Such, however, is not the case. We are inclined to let the *x*-ray picture point out some small area in the lung field that is causing all the trouble rather than to try and detect some minute change on auscultation, palpation or percussion that would prove our diagnosis.

Many a case of respiratory infection reaches the surgeon, occasionally, to be operated on, but many times sent back to the physician

*Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

for further observation because the symptoms do not warrant surgical interference. The same might be said of some abdominal cases in which slight tenderness and rigidity did not wake us up till a blood count made us realize the early *clinical* symptoms were decidedly important.

Proper time taken by the examining physician in a complete examination of the chest and abdomen would usually in spite of dire difficulties make a diagnosis possible.

The high temperature that usually accompanies a Pneumonia, the mode of onset, expiratory grunt, dilating alæ nasi, disproportion between respiration and pulse, and the thorough searching of the respiratory track will usually show some area presenting abnormalities.

If the chest fails to reveal evidence of infection, the careful examination of the abdomen, taking plenty of time to guard against unnecessary roughness and hurry, will show the abdominal wall free from rigidity, deep palpation will be negative and rectal examination will fail to locate a tumor mass.

In every sick child there is always exhibited certain symptoms referable to the illness with which the child is suffering and it is up to the attending physician to properly interpret these clinical symptoms rather than to let the laboratory attempt to do it for him.

There is probably no disease which is so commonly associated with abdominal pain as appendicitis.

Whether in the breast fed baby or older child so-called Colic has led to many mistakes.

In almost every instance the physician is called by the mother with the idea that the abdominal pain, stomachache, cramp or colic is entirely a problem having something to do with the feeding but the thought should always be uppermost in the mind of the physician as to the possibility of appendicitis or some other serious abdominal condition being present.

Appendicitis is one of the most frequent causes of abdominal pain.

It might be better to rearrange this statement in the following manner; Abdominal pain is always an accompaniment of acute appendicitis.

The pain is usually first located in the Epigastrium being colicky in type and rather persistent in character.

The child does not seem to be free from discomfort though the pain may not be continually acute. The tendency is for it to finally locate in the lower abdomen in the vicinity of the right rectus.

The pain seems to continue with periods of partial relief but even as the more definite sign of localization appears, pain still continues general as well as local.

Accompanying the pain, vomiting, muscular rigidity, localized tenderness, fever, rapid pulse, constipation, follow as a rule in rapid succession. The localization of the infection usually follows promptly somewhere in the vicinity of the McBurney point but it may vary according to the locaton of the appendix, as often shown by vesical irritaton and flexion of the right thigh in the abdomen.

The pain that may accompany Pyelitis usually is referred to some part of the genito urinary tract and signs of peritoneal irritation are wanting. The pain that accompanies Intussusception severe and paroxysmal in character occurring with vomiting, shock, complete constipation and bloody stools and with the other symptoms that make up the picture, present in the early part of the attack a soft relaxed abdomen very different from that of an acute appendix.

Abdominal pain occurring in an acute gastro intestinal upset usually ceases as soon as the intestinal tract is relieved of the offending elements.

Pain in the vicinity of the duodenum which may precede an acute jaundice is accompanied with very little tendernes and general disturbance.

In any infant or child, pain in the vicinity of the Epigastrium continuing off and on but fairly persistent with slight fever, occasional vomiting and constipation, should always be a warning of a possible appendicitis. There is no type of case in which hurry and carelessness in making the physical examination should be relegated so thoroughly and promptly to the background as in the search for the acute abdomen.

The difficulty many times of obtaining an accurate history has to be combated by a physical examination in which every physical finding no matter how trival must be carefully noted.

In this short paper it is not intended to go into detail relative to the many causes of abdominal pain.

It would seem to be much more important to point out the seriousness of abdominal pain and to urge that its warnings be heeded.

In dealing with the young it is always most important to remember the difficulties in obtaining an accurate history.

The busy mother absorbed with her many duties does not notice the first signs of illness, or if noted, a realization as to their importance is not appreciated.

The sick child may have been distressed a much longer period than observed by the mother. Many times, too, when a realiza-

tion of the seriousness of the illness does occur, she may for fear of censure for neglecting the child make an inaccurate statement in regard to the length of time the child has been ill. This has occurred to the reader rather frequently especially in reference to cases of Intussusception and has caused most unfortunate results.

In supposedly early cases a good prognosis has been made when on operation the findings prove that the child has been sick a much longer time than the history would indicate. In some instances, too, the mother has made the statement afterward that the child had been sick a longer time than she had at first stated.

This paper is to plead not only for more care in obtaining a history but in the physical examination as well.

The careful inspection of the sick child—noting every detail, should be done in good light, with patient and physician in as comfortable a position as possible so as not to unnecessarily tire either. Much can be gained by inspection. The type of breathing whether thoracic or abdominal, the movements of the chest wall, facial expression, color of the skin, appearance of the abdomen whether flat or distended, signs of gastric or intestinal Peristalsis, the position of the patient in bed, are all important matters. The careful examination of the child's abdomen in many instances is extremely difficult.

The irritable, peevish child, one who is extremely nervous or suffering from pain, may require great care in handling.

With proper judgment the physician can usually secure the cooperation of the child so that palpation and percussion can be carried out firmly and quietly as to detect signs of tenderness, rigidity, formation or any condition that would denote some type of abnormality.

It is time to not only keep on training our powers of observation but to *educate* our touch and hearing so that we will know when we feel and hear conditions that are abnormal.

It should be possible if we are persistent and careful in an examination of the sick child to take sufficient time to interpret our findings to make a correct diagnosis from clinical symptoms in almost every case.

THE INFLUENCE OF NUTRITION UPON THE RESPIRATORY INFECTIONS OF INFANCY*

By S. W. CLAUSEN, M.D., ROCHESTER, N. Y.

Introduction

RESPIRATORY infections present one of the most serious problems in pediatrics at the present day. In spite of the enthusiasm following the discoveries of Pasteur, bacteriology has solved this problem only in part. This failure is due to a too narrow conception of infectious disease, a conception which overemphasizes the importance of the invading microorganism, and ignores the invaded macroorganism. In all studies of infection, we must give due consideration both to the virulence of the causative organism, and to the resistance, absolute or relative, of the human host.

In studying the effects of nutrition upon infection, we are obviously dealing with a set of factors which affects usually the *relative* resistance. *Absolute* resistance or susceptibility is dependant upon a set of factors other than diet: in particular, inherited predisposition or immunity; immunity acquired by the host after successful encounters with pathogenic microorganisms or their products; or specific sensitization to disease, acquired by what we may term an unsuccessful encounter with pathological microorganisms. These types of immunity and sensitization seem to characterize what are known as the acute specific contagions of childhood; especially the exanthems, whooping cough and diphtheria. The science of bacteriology has furnished more or less satisfactory measures for preventing this group of specific infections.

The great group of nonspecific respiratory infections, so fatal in early life, against which no absolute immunity may develop, are best prevented by isolation. The problem before us for consideration may, therefore, be stated as follows: *Taking due account of exposure to infection, can we assign to good diet and nutrition any important protective effect?* We shall attempt to answer this question by reviewing the existing literature dealing with animal experiments and by presenting an analytical study of the records of hospital patients.

The obvious advantages of animal experimentation are as follows: (1) Exposure to infection can be controlled; (2) single elements in the diet can be varied at will; (3) due account can be taken of the age of the animal and the physical factors (other than diet) in its environ-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

ment. The most serious general criticism of this method is that inherent in all animal experimentation: *Do the results apply to man?* We must assure ourselves that the deficiency in diet with its resulting nutritional effect are in fact counterparts of the corresponding cause and effect in man; that the infecting organism and the resulting infections process correspond to a similar pair of causal and resultant factors in man. It appears that up to the present time, few if any controlled experiments have been conducted with human beings. With man, so many uncontrollable factors are at work, which lead to infection or to its absence, that we are obliged to rely upon the statistical method. This can never furnish the convincing proof or disproof of the protective effect of good nutrition, which can be obtained by controlled experiment—but does furnish us with practical suggestions for treatment and with a program for further investigation.

In considering the very extensive literature dealing with the relationship of nutritional disturbances to infection in experimental animals, one is at once impressed with the great significance of vitamin deficiency. Among the vitamin deficiencies, that of vitamin A seems of great importance. In order to illustrate this fact, we will cite a recent experiment of Bradford and Boynton (unpublished experiments). Bradford (1928) had isolated from lesions in rats dying of vitamin A deficiency a bacillus of the Friedlander group, capable of killing rats when administered in standardized doses by the intraperitoneal route. Groups of rats placed on the vitamin A deficient diet plus cod liver oil, were infected by intraperitoneal injection of the minimal lethal dose of the culture of the Friedlander-like organism. The time of survival of these animals was noted. It was shown that, in the protected group survival was more likely to occur; that lowering of resistance could be demonstrated at the 4th week, and that at the 12th week both control and low A animals never survived; and that at this time, the period of survival in both groups was much reduced. In order to compare the effect in animals with rickets, the Steenbock diet No. 3134 was used: controls received 0.01 mg. of irradiated ergosterol daily. Although pronounced rickets developed in the rats not so protected, there was no difference in the controls and affected animals until the latter were nearly moribund. These experiments emphasize the great importance of cachexia from any cause in lowering resistance; demonstrate that rickets per se does not lower resistance to this infection in the rat; and that the lowering of resistance to infection in animals on diets low in vitamin A can be demonstrated at a period before stationary weight is attained, and therefore long before xerophthalmia occurs.

Clinical Observations

Statement of the Problem: Does dietary deficiency predispose children to infection? In order to answer this question, we must prove the following propositions: (1) Certain children have received deficient diets; the deficiencies need not be absolute; (2) Children who have received such diets are more liable to infection than are children who have received good diets; (3) Either the two groups of children are comparable in other particulars or any differences which exist are such as to favor proposition 2.

There obviously exist other factors than diet which affect resistance to infection. This is particularly true in case of such contagious diseases as diphtheria, measles, smallpox, etc., against which known specific prophylaxis exists. We are concerned in this study rather with types of infection for which specific immunity does not seem to develop, particularly the respiratory infections.

Description of Clinical Material: The material includes all of the children who first entered the Strong Memorial Hospital or Rochester Municipal Hospital before their third year. Of about 1,000 such children, the records of some 300 have been analyzed, with special reference to the family history, the feeding history including particularly breast feeding, formulas of whole milk, dried or condensed milk, fruit juices, cod liver oil, cereals and vegetables; the presence of rickets, scurvy, anemia and underweight; the presence of rhinopharyngitis, otitis, mastoiditis, laryngitis, bronchitis and pneumonia. Forms were filled in so that the age and seasonal incidence of all variable factors could be graphically recorded.

Although such a study suffers from the inaccuracy inherent in all hospital records, it is felt that the inaccuracy of the data would probably be not much greater than the inaccuracy of statistical analyses in general.

The feeding histories are probably fairly reliable, especially in case of children under the age of 18 months.

Attention was paid only to the infectious processes actually observed in the hospital. In children under 3 years of age the number of specific contagious diseases is small, whereas the number of acute respiratory infections is very large.

Infection surely existed in our group much more frequently than it did in children who did not enter the hospital. In this sense, the group is not a fair sample of the juvenile population of Rochester. The children who were well-nourished probably enjoyed better general hygiene than did those badly-nourished; this fact may have been responsible for the lesser frequency of infection observed in this group. Moreover, the better-nourished children, who probably came from happier economic surroundings, would not enter the hospital unless really

serious diseases compelled them to do so. Therefore, very many of the children in this group had severe respiratory infections, in spite of an excellent feeding-history and good general nutrition. This means that the beneficial effects of good nutrition may be quite nullified if the individual is exposed to a sufficiently virulent microorganism. Such an infection in a badly nourished individual may seem no worse than in one well nourished.

Dietary Deficiency in the Children Observed: Cases of outspoken deficiency include scurvy and rickets. If deficiency of vitamin A exists it must obviously be of the relative type, the existence of which can be neither proved nor disproved by our present methods. If analysis should reveal a correlation between low intake of vitamin A and prevalence of infection, one might be justly criticised for concluding that relative deficiency existed and at the same time predisposed to infection, because unappreciated dietary factors (or others) might be involved. It is sound logic only to state the relationship itself; final proof could then be furnished by showing that in a similar group or in the same children, infections could be prevented by increasing the

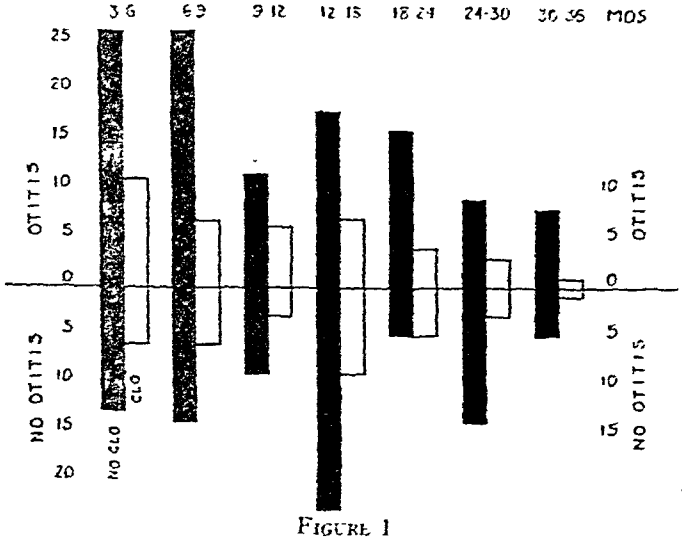

FIGURE 1

Effect of Cod Liver Oil in Preventing Otitis—The black rectangles represent the number of cases in various age-groups which did not receive cod liver oil before 2 months of age, or which received it in amounts less than half a dram per day. The white rectangles represent the cases which received cod liver oil before the age of 2 months, and in amounts more than a half dram per day. Doubtful cases are omitted. The portions of the rectangles above the horizontal line represent cases observed to have otitis media in the hospital; the portions below the line represent cases observed not to have otitis media. This chart fails to show that the administration of cod liver oil prevents otitis media.

intake of vitamin A. The sources of vitamin A in infant feeding are milk, green vegetables and cod liver oil. The latter, as usually purchased, is somewhat variable in vitamin A content, but it is believed to be a much more potent source of vitamin A than any other food used in our series.

We have, therefore, begun in the analysis of the data by tabulating infections in the groups which did and which did not receive cod liver oil. The results in case of otitis media are given in Figure 1. If one considered only the age-group 9-12 months, and only the cases having otitis, he might be led to conclude that cod liver oil prevents otitis. But by considering all children in the age-groups, it will seem that no really beneficial effect is to be expected from *cod liver oil alone in the prevention of otitis media.* If, however, our two groups are not strictly comparable in other particulars, this conclusion may not be valid; without further consideration, we would, of course, not be justified in dispensing with cod liver oil in infant feeding.

Consideration of the incidence of pneumonia shows what appears to be a somewhat more favorable effect from the use of cod liver oil (Figure 2).

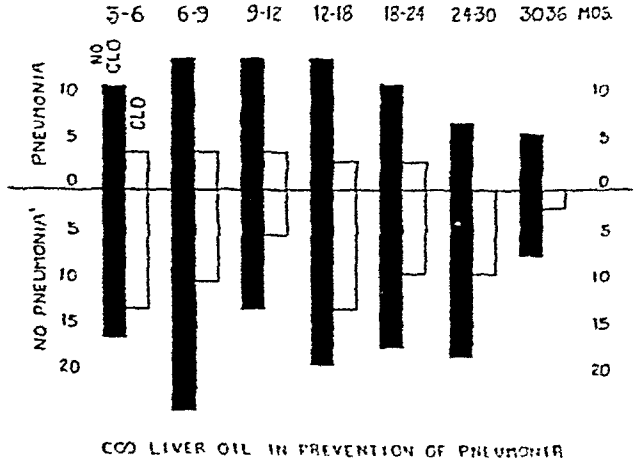

FIGURE 2

Cod Liver Oil in Prevention of Pneumonia—The method of representing cases which received cod liver oil and those which did not is the same as in Figure 1. The portions of the rectangles above the horizontal line represent cases observed to have pneumonia. The portions below the line represent cases observed not to have pneumonia. Doubtful cases are omitted. This chart fails to show that the administration of cod liver oil prevents pneumonia.

These two examples are given to illustrate what we believe to be a faulty method of analysis. For example, was the cod liver oil given in sufficient quantity, or are the records correct? If the infant developed rickets, one may assume for purposes of this analysis that an insufficient quantity of vitamin D has been absorbed; since vitamin A accompanied vitamin D, we will further assume—obviously as only an approximation to the truth—that the presence of rickets implies an insufficient intake of vitamin A.

In a purely arbitrary manner for the purpose of our study, we will assume that *bad nutrition* exists

(1) when cod liver oil was omitted after 6 weeks of age, or (2) when rickets developed, whatever the type of feeding, breast or bottle; (3) when the infant was premature or syphilitic or suffered from congenital heart disease. *Good nutrition* will be said to exist in all other cases. It will be seen that this comprehensive definition omits reference to weight, emphasizes the intake of vitamin A and provides for the inclusion under "bad nutrition" of those cases in which the vitamin A stores may have been low at birth (prematurity) or for some obscure reason may conceivably not have been well retained. The definition is doubtless too broad; but if with its aid we are still unable to observe a clear-cut effect on susceptibility to infection in "bad nutrition," the case for the influence of vitamin A will be seriously compromised.

The effect of good and bad nutrition upon the incidence of otitis media is shown in Figure 3

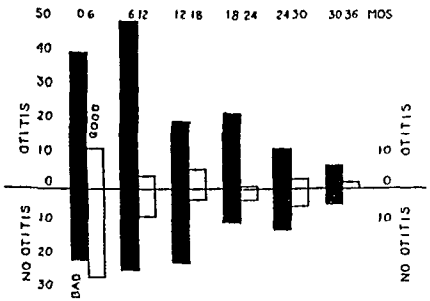

FIGURE 3

Bad Nutrition As a Cause of Otitis—The black rectangles represent the number of cases with bad nutrition as defined in the text (page 5 and 6). The white rectangles represent the number of cases with good nutrition. The portion of each rectangle above the horizontal line represents the number of cases observed to have otitis media; the portion below the line represents the number of cases observed not to have otitis media The chart shows that bad nutrition favors the development of otitis in the first six months of life, and perhaps in the first two years; but fails to show this effect in the third year. It is also obvious from the chart that other factors than nutrition are at work.

There is a fairly good correlation of bad nutrition with this infection in the first two years, and no correlation in the third year. This can be expected, because (1) we are able to get better dietary histories in the younger children and (2) older children are doubtless less dependent upon vitamin A, as is shown by the age-incidence of xerophthalmia with a maximum incidence at 6 months.

Nevertheless, the correlation is far from convincing. In Figure 4 is given the correlation between bad nutrition and "Severe infection." The latter is defined for our purposes as: (1) Mastoiditis, (2) pneumonia, (3) any infection (e.g., erysipelas) resulting in death. We exclude rhinopharyngitis, otitis, laryngitis and non-fatal bronchitis. We thus secure a much better correlation than before. In this, one would be inclined to see evidence for the thesis that relative deficiency of vitamin A is associated with severe infection. But in order that this conclusion should hold, it is necessary that the two groups—(bad nutrition, good nutrition)—either be comparable in other ways, or that any differences be such as to favor our thesis.

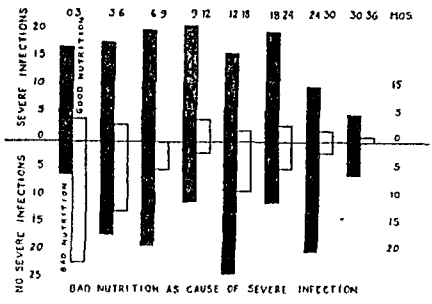

FIGURE 4

Bad Nutrition As a Cause of Severe Infection—The meanings of bad and good nutrition and of severe infection are those stated in the text. The method of representing the number of cases is that given in the note under Figure 3. This chart clearly shows that bad nutrition is a potent factor in the causation of severe infection in the first six months of life; and that good nutrition is a potent factor in the prevention of severe infections in the first six months of life. This effect is not clearly evident after the ninth month.

It can be shown that the two groups are not strictly comparable; e.g., Figure 5 shows the seasonal incidence of *all respiratory* infections in both groups. It will be noted that the badly nourished children develop many respiratory infections in winter; very few in summer; and a considerable number in September and October. The well-nourished children, on the other hand, develop most of their infections in the late spring months and very few in summer or in September and October. The infections in winter months are almost invariably severe. This is probably explained by the fact that this group of children are somewhat better cared for, and are not usually brought into the hospital for the milder infections. It is, therefore, a differently selected group from that with "bad nutrition." Can we show that a factor operates in the group with good nutrition which is likely to overcome the effect of the good nutrition in preventing in

fections; and that this factor operates to a lesser extent in the group with bad nutrition? If so, weight is added to the arguments already given to support the hypothesis.

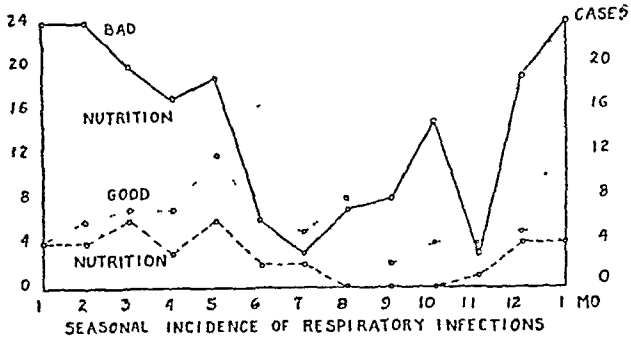

FIGURE 5

Seasonal Incidence of Respiratory Infections—Ordinates denote number of cases. Abcissas denote months numbered according to their order. Good and bad nutrition are defined in the text. Only cases with respiratory infections are shown:

o——o denotes cases of bad nutrition having any res. inf.
o. . . .o denotes cases of good nutrition having any res. inf.
o- - -o denotes cases of good nutrition having severe res. inf.

It is evident from this chart that the seasonal incidence of respiratory infections is strikingly different in the cases with good and those with bad nutrition.

The severe infections are usually acquired from other persons. If there are older children in the family, the chances of severe infection developing in the younger children are much increased; in the age-group in question the transmission of an infection from younger to older children is less likely to happen. Analysis was, therefore, made to correlate the presence or absence of "severe respiratory infection" (Mastoiditis or pneumonia) with the presence or absence of older children in the family. There is a very striking difference in the well-nourished and in the badly nourished group. Figure 6 at once suggests: (1) Many infections in both groups are closely associated with the presence of older children. (2) This factor is much more important in the well-nourished group. Unfortunately, the number of cases is too small to permit a more detailed analysis.

CONCLUSIONS

It may be concluded, therefore, that two factors are clearly at work in the production of severe respiratory infections in young children: (1) The presence of virulent organisms in the child's environment. This factor depends especially upon the presence of older children in the family. This factor is so powerful that it can overcome any beneficial influence of good nutrition. (2) Bad nutrition. Our results suggest that a number of dietary factors are involved, among them rather conspicuously vitamin A; but we would emphasize that the situation is more complicated than the presence or absence of vitamin A in the diet; and that at present we are justified only in considering "Bad Nutrition" as due not to one but to many factors.

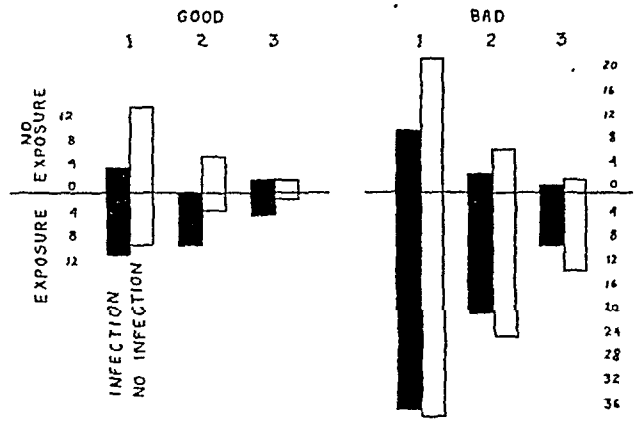

FIGURE 6

Severe Respiratory Infections in Groups of Children With Good and With Bad Nutrition As Associated With Exposure—The black rectangles denote the number of cases observed to have severe infection. The white rectangles denote the number of cases not observed to have severe infection. The portion of each rectangle above the horizontal line represents the number of cases not exposed to an older child in the family. The portion below the line represents the number of cases in which there was an older child in the family. Cases of good nutrition are represented by the three groups of rectangles on the left; cases of bad nutrition, on the right. The age groups: 0-1 year, 1-2 years. 2-3 years are separately represented.

It is apparent that no correlation exists in the badly nourished children between severe infection and exposure to an older child, whereas a striking correlation exists in the well-nourished children, and this correlation is apparent through the second year at least.

Finally, the results of animal experimentation and of clinical experience may not yet be convincing, but they do permit us more definitely to formulate a problem for further research. Under specified conditions of exposure to infection, can we, by proper administration of vitamin A lessen the liability to infection, or moderate its severity?

One important practical conclusion follows from this study. At the present time, when propagandists are urging the use of irradiation for the prevention of respiratory infections, and the substitution of visosterol for cod liver oil, we should demand adequate proof of their claims. We have good reason for advocating cod liver oil for every infant.

PHYSICAL THERAPY IN GENERAL PRACTICE*

By C. E. ANDERSON, M.D., ELMIRA, N. Y.

PHYSICAL THERAPY must be based upon a diagnosis that is founded on a careful physical examination and laboratory procedure. It must be based on a thorough knowledge of the physiology and pathology of the given morbid condition.

Its greatest use is as an adjunct to other well organized procedures used in medicine and surgery, and this combination has increased the efficiency of therapeutics as a whole most markedly.

It should never displace other proven methods that may be superior.

Physical therapy demands as much training as surgery or medicine. Yet, I am afraid, there is a tendency to entrust this type of therapy to an aide or nurse with no real supervision and oftentimes without sufficient thought and diagnostic procedure. This is the most glaring fault attending physiotherapy among a few of our practitioners and that invariably is the reason why some of our profession are disgusted with physiotherapeutic results.

The question of equipment: The remark of a personal friend still rings in my ears; who exclaimed, "I believe I can get more results with an excellent masseuse and a heat lamp than without a masseuse and all the equipment in the world."

I know the most necessary equipment of a department is, first, a masseuse. If she does not know electrotherapy, certainly you can teach her that yourself if you are conversant with your own equipment, and it will not take long before she can apply these modalities as well as you can. But all the beautifully trained so-called physiotherapy technicians in the world can not get maximum results with patients unless they know and practice real massage; of course, we take for granted that a masseuse knows anatomy.

These technicians must be efficient, pleasant, cheerful, and above all, encouraging. This may be a lot to ask of one person but if you have such a one, your physiotherapy results are bound to be commensurately satisfying.

Of course, the first piece of equipment is invariably a heat lamp, one with an interchangeable infra-red unit and incandescent bulb. Perhaps next an air-cooled mercury quartz ultraviolet lamp. In my observation and personal experience, a water-cooled lamp has not enough uses in general practice to justify its expense. I have nothing detrimental to say about the carbon arc, but in a busy practice, time is a factor which would make a choice in favor of the quartz light.

Added to this a high-frequency machine, preferably one that can be adjusted to the most delicate dosage yet if necessary strong enough to produce heavy coagulation. Diathermy is a most useful modality and may be employed in almost every condition where inflammation exists, barring first a tendency to hemorrhage and secondly, the presence of undrained pus. This second contra-indication is put aside if drainage is established.

The foregoing equipment provides an adequate start and if the practitioner appreciates the limitations of this minimum equipment, it will suffice for most of his applicable cases. However, if his interest increases and his type of practice warrants it, galvanism and sinusoidal current can be added, and then perhaps whirlpool baths for the arm and leg. Static electricity still has its voters.

A few years ago Dr. Granger allowed me to wander for a number of weeks about his clinic at the Boston City Hospital. While there, he stressed the point that convalescent patients need encouragement; that the slightest improvement be noted and the fact drawn to their attention; that an atmosphere of cheerfulness was very important. The psychic side of physiotherapy, as in every field of medical practice, should never be neglected.

The room, or rooms, used for this purpose should be efficiently lighted and ventilated, its decorations, curtains designed to give a restful cheerfulness. Privacy should not be overlooked.

Dr. Wm. McFee, of Boston, tells us in regard to treatment that "If we are students of our work, our experience and observations will tell us the technique we should follow, and this must depend upon the equipment available to our use and our knowledge of the quality and quantity of current which it can be made to produce so that in all treatment by diathermy the exercise of individual judgment is all important. We cannot depend entirely upon following a rule. This must be our procedure until such time as physicians are able to get and use equipment with a common standard of current quality, quantity, control, and measurements."

The above quotation not only applies to diathermy but to every piece of equipment used in physical therapy. Given for example a known pathological condition, the knowledge of the possibilities of your equipment will present themselves, if applicable.

In physiotherapy a single modality can be used

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1930.

in but a very few indications. The right combination of mutually helpful and complementary measures is the key to successful treatment. This does not include the physical modalities alone but the proper combination of all methods of treatment applied to a given pathological condition.

I would not filch the prerogatives of later speakers by discussing at length the technique of physical therapeutic appliances, but I do not think it would be amiss to mention the use of ultra-violet in the asthenic patient.

Many patients come to my office in a year's time with a low resistance, no definite active objective symptoms, but tired, exhausted with the stress and worry of earning a living; certainly presenting the picture of dejection; in splendid shape to receive the first invading organism and provide soil for its rapid multiplication.

Physical and laboratory examinations do not reveal that these patients are hyperthyroids in type; not active pulmonary tubercular patients, nor are they diabetics; and we may also exclude the arterio-sclerotic myocardial nephritic types.

Often the only positive sign may be a low hemoglobin, but these cases have been a very active problem.

Ultra-violet combined with the indicated medical therapeutics have picked up these patients beautifully. Radiations are kept well below an erythema reaction given every second day. Their mental depression and physical exhaustion improve in a very rapid and satisfactory manner.

Our calcium deficiency cases also respond in the same gratifying way.

I believe that we do not spend enough time in producing adequate medical care in these very common non-spectacular border-line cases. Here physical therapy in its broader meaning finds a most efficient field. It provides us with a most helpful means of raising resistance in almost any of our prodromata as well as our convalescent cases.

The general tonic effects of ultra-violet are becoming very well recognized by the general public. This has been brought about at least in part by the various companies producing ultra-violet lamps for the home.

Some of the lamps contain little or no ultra-violet; others do produce an appreciable amount; how much we cannot determine for our erythema reaction after all is by no means an accurate scale of ultra-violet.

I know that these lamps in the majority of instances will have no medical supervision; also that a certain percentage of our doctors do not know or recognize the dangerous weapon ultra-violet may become in unfamiliar hands.

I have seen some early cases of pulmonary tuberculosis fulminate under the injudicious use of ultra-violet. A number of hyperthyroids have become markedly exaggerated. One diabetic has passed into the beyond, and a large number of our senile cases with arteriosclerosis. Myocardio nephritic symptoms have done far from well with its use.

So let there be some publicity to this effect that these cases upon which treatment is to be used by lamps sold at the door be first supervised by a physician familiar with ultra-violet and, second, that the actual amount of ultra-violet emitted be accurately stated. Or what is a thousandfold better, keep the sale of these lamps under the control of physicians' prescriptions. In our own rural districts they are being loaned about the community like a prescription for stomach powders.

In the field of orthopedics and industrial surgery, physiotherapy is an indispensable adjunct to bring about maximum functional restoration.

Seventy-five per cent of physical therapeutics in a general practice will find employment in the realm of minor bruises, contusions, hematoma, sprains, ligamentary and muscle strains, etc., with a minimum amount of time lost to industry.

In the after-care of fractures and treatment of non-union, physiotherapy has found a field that in itself alone would find ample justification for its existence. Arthritis and synovitis, periarticular adhesions and scars, atrophies, upper and lower neuron lesions find physiotherapy a marked help in restoration.

The field of industrial surgery could not have reached its present efficiency without these modalities.

In conclusion, let it be said that in physical therapy every case is a distinct problem. It will vary in its type of treatment with each subject. After all, it is not so much what we use as how we use it. It must be used after a careful physical and laboratory examination. A correct diagnosis must be made. And use it only in such cases as we may anticipate some benefit.

I can do no better than quote from Dr. C. P. Hutchins' paper to the effect that "It is of real value when used as an adjunct to medicine and surgery, but it is not a panacea; neither is it a dump. Physical measures are not specific. The instruments and methods we have been discussing are entitled to just recognition for faithful accomplishment. They will acquit themselves just so far and so truly as their application is conceived in rational therapy. They are as precise as the scalpel and castor oil when guided by the same knowledge. But no amount of engineering or manual skill can atone for immature or faulty judgment."

THE JOURNAL FOR 1931

A brief note of appreciation from an officer of the State Society states that the January 1st JOURNAL was the most interesting of all the numbers that have been issued The probable reason for that opinion is that the record of the activities of official medical societies was unusually large, filling nineteen pages—two of the editorial section, ten of the news department, and seven of the section called Our Neighbors

The editors are not responsible for the intrinsic interest of the records—that depends on the activities themselves But the fact is that the medical societies are doing things which are of vital interest to the physicians themselves and also to the public. The editors will have no difficulty in making the JOURNAL interesting and practical so long as the leaders of the medical societies continue to do things which are worthy of record

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—NO. 14

On page thirty-seven of the January 1st issue of this Journal there is a report of a plan offered by the Bassett Hospital Guild for supplying medical service to practically every person in the small city of Cooperstown, Otsego County, N. Y., on essentially an insurance basis.

There are two general classes of insurance—commercial and social. The Bassett Hospital proposal is nearer commercial insurance than social insurance. It is based upon the same kind of principles that fire insurance is based upon and which nearly everyone uses for the purpose of distributing individual losses among a group. Everybody understands the value of commercial insurance.

Is this proposal only a plan to distribute the expense of sickness so that the burden may be borne by the well as by the sick, as the plan states? Is there any thought behind the plan to give to the person whose income is insufficient to provide for himself anything more than the barest necessities, some means of not leaving him totally unable to provide for the cost of sickness?

This proposal has no limitation of service, except obstetrics, chronic diseases, and roads difficult of access to the patient. There is no reference to the financial status of the individual. One well-to-do may become a member as well as one of limited financial resources. If the proposal were to be confined to the wage earner who has little or no surplus after providing the necessities of life and, therefore, could afford to pay little for sickness or not at all, it would be quite different from including the moderately well-to-do person who becomes a member of the Guild only because he finds it profitable to do so. There would then be different viewpoints of the plan which, as it stands now, includes everyone who can pay twenty-five dollars a year and without regard to his financial ability. This plan, of course, gives financial security in future sickness just as an insurance policy gives financial security from the danger of one's house burning down. It does not seem to consider, however, the results of inability to do profitable work and the poverty that comes because of inability to work because of sickness.

This proposal does not undertake to meet any underlying need of poverty from sickness or to meet any disturbed economic state that comes from insufficient wage income, unemployment, or other cause. The proposal is not, therefore, social insurance as the world understands social insurance. One, therefore, wonders just what the object is behind the proposal. Is it to give better health service than the individual would have if he had to pay for it by fees, since it does not seem to imply a charity service? It seems that it is meant to apply equally to those who have ability to pay their bills for sickness and who may find it financially better to adopt this form of commercial insurance, and to those who have limited financial resources.

I do not know that there is a basis of exact knowledge as to the cost of sickness. One wonders if twenty-five dollars a year will cover the cost of the health and sickness service that an individual should have, or that it will cover the cost of the service that an individual will believe necessary when he has paid in advance for the care of all the sickness for a year.

There is some public interest in sickness insurance. This field has not been well thought out in this country. Its weaknesses and limitations are not known in America. Its soundness or unsoundness will come out, perhaps, in the proposed experiment at the Bassett Hospital. The proposed plan will have some value in showing what the facts really are. If this experiment succeeds, it will diminish personal, financial insecurity. It does not seem as if it would do anything else. On the other hand, it may diminish personal watchfulness of health. It might diminish personal interest in preventing illness. It undoubtedly would encourage a patient to go more often to a doctor. This might be a benefit to the patient. One wonders if it would increase malingery.

The medical profession is not sympathetic toward any plan of insurance that would tend to diminish personal, professional responsibility. The merits and demerits of this Guild proposal should be observed and the profession should avoid the temptation to decide upon it now.

We have at the present time a Welfare Law that in time will properly grow into perfection of administration that will take adequate care of the indigent. This is supported by general taxation and the burden, therefore, is evenly distributed.

There are no legal objections to the proposal to give sickness service for a year at a definite price. It is legal to practice medicine by means of a guild. It does not come under the head of practice of medicine by a corporation. It is therefore, I am informed, within the law.

This matter was referred to the Public Relations Committee of the State Society. This Committee has discussed it exhaustively. It has reached the conclusion that the matter should have open minded observation; and it will report to the Society from time to time or whenever conclusions can be reached.

The objections are plain to the profession. It seems, however, that it would be better to avoid the temptation to draw conclusions from the proposal at this stage than to condemn the proposal without the equivalent of a hearing.

WILLIAM H. ROSS, M.D.

ANNIVERSARY OF FIRST MEDICAL PRACTICE ACT

April 4, 1931—less than three months ahead—will be the one hundred and twenty-fifth anniversary of the enactment of the first medical practice act in New York State. This law authorized the qualified physicians of each county to organize themselves into a county medical society for the purpose of examining and licensing candidates for the practice of medicine. Also the law provided that delegates from the county societies should meet and organize a state medical society, which they did on February 2, 1807. This state society had the same powers as its component county societies, and in addition could license candidates and also act as a board of appeal if a candidate were rejected by a County Society.

The editors of this Journal desire to collect and record the history of the founding of the county medical societies, for very little has been published on the subject. Diplomas and licenses issued by the county societies will be especially valuable and interesting. On page 107, there is reproduced such a license issued by the Delaware County Medical Society in 1813 to Dr. Luther Appley, whose descendants of the third and fourth generation are still practicing medicine.

This Journal of February 1st will contain a reproduction of a license issued by the Suffolk County Medical Society in 1807 to Dr. Nathaniel Miller

This Journal of November, 1924, page 958, printed a reproduction of the first page of the minute book of the Washington County Medical Society, recording its organization on July 1, 1806, with twenty-two members. This book is still used to record the minutes of the society.

The Medical Society of the County of New York contains a mass of unpublished material including a book in which are recorded the details of the examinations of individual candidates—the questions asked and the candidates' answers.

Several county societies are planning to celebrate the one hundred and twenty-fifth anniversaries of their founding, and the histories of these societies should be published in the Journal.

The editors will welcome any information regarding historical material, and will try to follow up suggestive leads and rumors.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

A.M.A. Biographical Index: One of the great services rendered by the American Medical Association is the preparation and maintenance of a current biographical index of every physician in the United States. This is the "Book of Life" of the medical profession wherein is recorded every medical act a doctor has done, be it good or bad, or indifferent. It is from this book that the data are obtained for the exposure of quacks and illegal practitioners; but the virtues of good doctors are recorded with equal care and fullness. The installation of this index was described in a two-page article in this Journal of January, 1906, as follows:

"A biographical card index of the medical profession has been established, and it is hoped that very soon this index will contain a card for every physician in the United States. On the card will be recorded name, place and date of birth, preliminary education, medical college and year of graduation, state license and data, medical societies, college and life insurance positions, school of practice, and specialty, if any. In connection with this fundamental information, provisions are made for recording removals, positions held and other matters that may occur in the life of the individual that are of sufficient medical interest to note. Such information is pouring into the general offices of the Association from state and county societies, from licensing bodies, from newspaper clippings, the last alone averaging over one hundred and fifty a day. Through the cooperation of medical colleges and State boards, certified lists of graduates and licentiates, together with most of the personal information requested, have been obtained and are now being properly classified. There is now in possession of the Association a fairly complete list of graduates of American medical colleges from 1860 to 1901. This list has been supplemented and brought up to date through the coöperation of registrars and secretaries of medical colleges. Copies of the official records of more than three-fourths of the licensing bodies have been secured. The remaining records are now being copied and will soon be completed. Blanks for reports both of colleges and of licensing boards have been prepared.

"The second reason for desiring this information is for use in compiling a reliable and accurate directory. The directory, however, is only incidental to the other work. From the index will be drawn information, either personal or official, for compiling, revising and correcting the directory, for the one now in preparation, as well as for subsequent editions."

MEDICAL PROGRESS

Post-Operative Coronary Occlusion.—Osmer S. Randall and Thomas G. Orr, writing in the *Annals of Surgery*, December, 1930, xcii, 6. report two cases of coronary occlusion following operation. Both patients were males, aged 58 and 60 years, respectively, showing definite evidence of arteriosclerosis, but neither gave any history of angina pectoris. In one case examination revealed an irregular pulse with what were apparently extrasystoles and a pulse pressure of 160 systolic and 110 diastolic. The blood pressure in the older man was 95 systolic and 60 diastolic and the pulse was regular. In the younger man death occurred on the fourth post-operative day; in the old man symptoms of occlusion occurred on the eleventh post-operative day. Evans has pointed out that post-operative thrombosis in general manifests itself most frequently at an interval of some days after operation. He notes that blood platelets rise following operation, reaching a maximum in about ten days, and then decline to normal. After operation there is also a rise in blood-fibrinogen, apparent on the third day and lasting until the tenth day. The increase in these two important elements of clotting following operation explain why surgical patients may develop thrombosis or embolism about the tenth post-operative day. It might be possible in certain cases to avoid post-operative catastrophe by taking a careful cardiac history prior to operation to exclude angina pectoris as a predisposing cause of post-operative coronary occlusion. Every effort should be made to prevent shock by proper selection of anesthetic and operative technique. In order to combat the decrease of metabolism, the fall in blood pressure, and the slowing of the circulation 2-grain doses of desiccated thyroid may be given three times daily. In addition the diet should be carefully regulated since food intake bears an important relation to coagulability. Protein diet increases coagulability while carbohydrates and fats have the opposite effect.

The Anatomical Result of Peri-arterial Sympathectomy.—As the results have been notably varied in all the conditions in which peri-arterial sympathectomy has been tried, D. M. Blair, D. Duff, and J. A. Bingham undertook the present investigation in order to gain more precise knowledge of the origin, distribution, and function of the vasomotor nerves. They studied the condition of the nerves in the main arteries in a leg amputated five weeks after a peri-arterial injection of alcohol into the sheath of the femoral artery. All the nerves running with the artery at the seat of the previous operation appeared to have degenerated distally, but an abundant additional supply running to the vessels lower down from the ordinary nerves of the limb then showed up in marked contrast. This accessory nerve supply had arrived upon the vessels of the leg mainly in the popliteal space. The incidence of these accessory nerves was also checked by anatomical dissection in another limb. The findings in the dissected and "experimental" limbs corresponded fairly closely, and were in general agreement with the results obtained by Potts in dissections of nerves to the arteries of the leg. Neither the authors nor Potts observed any vascular twig coming from the obturator nerve in the thigh. It seems a pity if the only vascular nerve in the leg which is mentioned in the ordinary text-books of anatomy has to be dropped. The incoming accessory nerves have a characteristic structure, being composed chiefly of small medullated fibers, with a few large medullated fibers and a fair number of non-medullated fibers. Evidence is adduced which suggests that the incoming nerves to the vessels in the limb may be specially concerned with the vascular supply to the muscles. The chief result of the investigation served to emphasize once again the dual paths of the vascular nerves to the limbs. It is obviously impossible to influence the whole of these by any proximal operation of peri-arterial sympathectomy. Hence the preference of American surgeons (Davis and Kanavel) for cervical or lumbar sympathectomy.—*British Journal of Surgery*, October, 1930, xviii, 70.

Low Blood Pressure.—Although the study of hypotension is still young in comparison with that of hypertension, it is already possible to establish the clinical picture of essential idiopathic hypotension. Wasserthal of Carlsbad, after a study of blood pressure covering 20 years, has been impressed with the increasing frequency of hypotension since the War. It is of course self-evident that a large proportion of patients at Carlsbad are suffering with gastric ulcer, gall-bladder disease, and ptoses of Stiller or Kretschmer type, but Wasserthal's statistics do not include any highly asthenic subjects. In several patients in whom hypertension had been observed over a long period, hypotension appeared without any evident cause. Similarly in a number of women who had been rendered sterile as the result of operation, a very marked hypotension was present with conditions of health otherwise entirely normal. These are phenomena of which the cause remains obscure. Without formulating any hypothesis, it is perhaps pertinent to recall analogous phenomena such as the in-

creasing frequency of anacidity and hypochlorhydria in former soldiers of the central venereal unit of the troops of Cracovia, observed in the winter of 1916-1917. Similar observations had been made by a number of other writers. On the other hand, there has been a disappearance of chlorosis, for which no theory has been suggested. Another analogy is the increasing frequency of venous thromboses, both spontaneous and postoperative. Excluding all cases of morbid hypotension due to anatomic, functional, constitutional, or familial factors, one must recognize that in recent years there has been a significant increase in the number of cases of hypotension of unknown causation in persons enjoying good health and even participating in sports. To this hypotension Wasserthal has given the name *hypotonia innocens*. It is important to recognize the frequency and harmlessness of this condition in order to avoid ill founded phobias due to too pessimistic a conception of the hypotensive state, and to prevent useless interdictions with regard to walking, engaging in sports and making use of baths and mineral water cures.—*Archives des maladies du coeur, des vaisseaux et du sang*, October, 1930.

Abuse of Tobacco and Coronary Sclerosis.—On the basis of two fatal cases in which coronary sclerosis was directly attributable to the abuse of tobacco, Karl Plenge writing in the *Deutscher medizinische Wochenschrift* of November 14, 1930, comes to the conclusion that it is not very unusual for nicotine to exert a toxic effect upon the coronary arteries. In both the cases at autopsy an arteriosclerosis was found, limited to the coronary arteries, especially evident in the ramus descendens of the anterior coronary. That these were not cases of ordinary arteriosclerosis is shown by the fact that such vessel regions as the aorta and the cerebral and renal arteries were practically exempt from involvement. The only respect in which the histologic findings differed from those of atherosclerosis was in the striking participation of the tunica media, in which in addition to cicatrices of connective tissue at places where muscle fibers and elastic elements had been destroyed, there could also be demonstrated entirely fresh necroses. The anamnesis and course of the disease pointed to a connection between these findings and the immoderate use of tobacco. Nicotine has long been recognized as a spasm producing poison. It acts through the mediation of the vagus upon the vasoconstrictors and thus induces a state of spasm, which leads at first to purely functional disturbances, but in course of time it also produces anatomic changes, both in the heart muscle and also in the arteries themselves. There is no doubt that angiospasm, even though sustained only for a short time, can produce such changes in the heart musculature that necroses and cicatricial indurations result. Cardiac aneurysms may then be produced which end in the formation of thrombi. Under these conditions thrombotic and embolic plugs may easily enter the coronary arteries, usually causing sudden death, this depending on the size of the vessel and the presence of anastomoses. In one of the cases described embolic closure of the ramus descendens caused sudden death while in the other the heart was slowly paralyzed as the result of vessel injury and of the severe myomalacia. Experience proves however, that sensitivity to nicotine varies in different individuals—a fact probably due to a constitutional cause, partly somatic and partly psychic.

Treatment of Angina Pectoris by Angioxyl.—C. Dimitracoff makes a report on 10 cases of angina pectoris in which he has employed the new desinsulinated pancreatic extract angioxyl of P. Gley and N. Kisthinios. In 9 of these cases the efficacy of the product was beyond dispute. An especially brilliant result was obtained in a case in which the patient was also suffering with duodenal ulcer and high blood pressure, all 3 conditions yielding to 18 injections of angioxyl. Not only did the extract relieve pain but its effect on the mental state of the patients was very striking, causing renewed courage and will to live. Only in the 10th case, in which aortitis and dilatation of the left ventricle were added to angina pectoris, did angioxyl prove ineffective. Here it produced only slight temporary relief, and in time the symptoms of decompensation and dyspnea returned with the anginal syndrome, despite a new series of 10 injections. Here, however, the pain was due more to the inadequacy of the left heart and the administration of ouabain and digitalis produced excellent results, although only temporary. In angina from effort and angina in decubitus the results were the same. In most cases a treatment of 20 intramuscular injections was sufficient—the patient receiving at each injection the contents of 1 ampule that is, 20 hypotensive units. This produced cures lasting 3, 4 or 5 months. In only one case was it necessary to give 2 and 3 ampules per injection.—*Progrès medical*, October 25, 1930.

Ultraviolet Light in the Treatment of the Dull and Backward Child.—Frank Sugden, writing in the *British Medical Journal*, November 29, 1930, p. 3647, states that he has been greatly impressed by the improvement in the mentality of many children receiving ultraviolet light treatment. The puling, querulous irritable, anemic self centered sleepless child who is often

pot-bellied and emaciated, is transformed into a robust, well-nourished, and perfectly healthy little animal, full of life and gaiety; all this happens within a few weeks. He cites the case of a boy who was miserable, sickly, nervous, lifeless, and with little interest in anything. He was treated with the mercury vapor lamp, exposures being given, both front and back, at a distance of 30 inches. The durations of the exposures were as follows: March 21st, three and a half minutes; March 24th, five minutes; March 28th and April 1st, seven and a half minutes; ten-minute exposures were given seven times during the month of April. Under this treatment the boy really began to live and enjoy life like a normal child, and made much more rapid progress educationally. He developed an interest in games, learning to swim and dive, concentrated better on all his work, and became much more cheerful. This case, the author states, is not unique. He has had many results equally satisfactory, and he cannot urge too strongly that those who have to deal with this type of child institutionally should give the ultraviolet light treatment a fair trial. It is reasonable to assume that mentally retarded children of the better classes would likewise benefit by this treatment.

The Medical Treatment of Anthrax—C. G. Brentnall compares the results in 11 cases of anthrax treated surgically during 1927 and 1928 with the same number of cases treated medically during 1929 and 1930. The two series of cases were similar as regards the site and severity of the infection. Of the patients treated surgically 8 were cured after an average hospital stay of 32.8 days, while of the 11 cases treated medically 10 were cured after an average hospital stay of 9 days. Anti-anthrax serum was employed in doses of 40 to 200 c.c. together with a daily dose of 0.6 gm. of stabilarsan or a single dose of neosalvarsan. Organic arsenic, if used, should be given in large doses. Smaller doses do not seem to have sufficient therapeutic effect to justify their use, and their cumulative effect is probably as dangerous as that of one or two large doses. Staphylococci appear to assist in inhibiting the growth of the anthrax bacilli in the cutaneous lesions. The presence of pus is not necessarily a contraindication to the existence of anthrax in a lesion. The bacteriology of the "pustule" is unreliable as a guide to the progress of the disease. Anthrax meningitis is apparently insidious in onset, and may be more common than is usually suspected. It might be well to look for nervous symptoms in all cases, and not to spare the use of lumbar puncture for both diagnosis and treatment. It is possible that by such means the heavy dosage that is occasionally necessary might be much diminished. From a study of the 22 cases in these groups the author finds that among tanners, cutaneous anthrax tends to occur more frequently during the winter and spring, and at such seasons mainly among those employed on dry hides.—*The Lancet,* November 29, 1930, ccxix, 5596.

Dietetic Treatment of Tuberculosis—To form a correct judgment of the value of dietetic treatment of tuberculosis, B. Köhler says it is necessary to have a large clinical material under personal observation over a long period of time. During a period of 2 years he has had an opportunity at the Munich Surgical Clinic to observe the results in 200 cases of tuberculosis involving the skin, bones, joints, or soft parts. The shortest period of observation was 2 months, but in most cases the observations covered a period of over 6 months and in many instances 12 months or longer. The form of diet employed was strictly that of Hermannsdorfer, which, like that of Gerson, omits salt and increases vitamins, but differs from the latter in allowing 600 grams of meat per week and in preserving a slightly acid character. The Hermannsdorfer regimen also doubles the protein content of the diet and recommends the administration of 160-200 grams of fat daily, while restricting carbohydrates to 220 grams per day. It gives dry food on the ground that the limitation of fluid to a minimum, together with salt withdrawal and carbohydrate restriction, leads to a general desiccation, and restrains the growth of agents causing inflammation. In some cases heliotherapy was also carried out. To overcome the insipidity of a salt-free diet a salt of bromine was used as a substitute. The benefits from this dietetic treatment are incontestable in lupus and skin tuberculosis. Not one case among the 13 observed failed to respond favorably. The results were equally good in tuberculosis of bones, joints, or soft parts if the cases were not too far advanced. In closed cases the patients took on weight, local pain and swelling regressed, and in the roentgen picture atrophy gave place to increased calcium content, and blurry outlines became clear. Fistulous cases also resulted in cure and cicatrization, when the focus was circumscribed and the discharge relatively slight. But in severe purulent cases of mixed infection with breaking down and exudation the dietetic treatment had little or no effect. As to conclusions founded on a study of 75 cases of pulmonary tuberculosis, Köhler reserves judgment until more time has elapsed. It must be emphasized that dietetic treatment can be successful only provided the dietary service of the hospital is organized exactly according to prescription. In cases of surgical tuberculosis the expert attention of a surgeon specialist must never be relaxed during this treatment. Emphasis is laid upon the recommendation that the dietetic treatment be carried out only in special wards reserved for this method. —*Münchener medizinische Wochenschrift,* October 24, 1930.

The Prolongation of Life.—Although the physician, of course, prolongs life in individual cases, Oliver H. Howe questions whether he prolongs the collective life of the race. The average length of life has increased from 33 years in 1800 to 59.1 years in 1929, but this is largely due to control of the diseases of childhood and adolescence. Insurance tables of expectation of life show little or no gain after the age of 30. It is a reproach to our profession that the period between 30 and 70 years has not recorded any advance in expectation of life. Deaths from heart disease, cancer, pneumonia, and Bright's disease account for 48.5 per cent of all deaths. The vast amount of experience, experiment, and research has provided us with a host of new resources and remedies, but they are not applied except on a wretchedly small scale. Few of the great discoveries of preventive medicine, except the prevention of yellow fever, are anywhere nearly fully applied. The stress of American life is an important factor in wearing out vitality. Some forms of heart disease, as well as arteriosclerosis and Bright's disease, seem to be connected with the wear and tear of life. The physician has an opportunity to know the daily activities of his patients and to advise them in many helpful ways, so as to reduce this wear and tear. Periodical health examinations may reveal some unsuspected conditions in the incipient stage, when they can most easily be remedied. The greatest care must be used, however, to avoid making the patient morbidly alert about his health. As no one man can possibly keep abreast of the field of internal medicine (to say nothing of other fields) consultations should be more frequent than they are. During the past twenty-five years the average age of physicians at death has increased from 60.3 to 64.9 years. This increase, Howe believes, is partly due to better care on the part of physicians of their own health and vigor. If they have any secret they should impart it for the benefit of their patients. Besides regulating the physical welfare of their patients, physicians have an unusual opportunity so to influence their minds as to assist every healing process. The physician should act as "guide, philosopher, and friend." This requires that he should individualize his patients, he should visualize their daily experiences, and see that they get the best things out of life. There can be no question that it lies within his power—and it is his manifest duty—to reduce the number of disheartened and discouraged people who, unassisted, may go down to untimely graves. By such services he may hope to prolong the average life of the human race.—*New England Journal of Medicine*, December 18, 1930, cciii, 25.

Normal Structure of Endometrium and Decidua and the Menstrual Cycle.—John H. Teacher, reviewing the orthodox theory of the menstrual cycle, says that in its extreme form this theory asserts that: (1) there is no menstruation without ovulation—ovulation must therefore go on all the year round in the absence of pregnancy or disease; (2) that ovulation occurs about the middle of each cycle dating from the commencement of the bleeding; that the ovaries work month about. To this theory he takes exception, preferring that of Heape formulated more than thirty years ago, and recently confirmed and made more precise by G. W. Corner, Hartmann, and others. Heape's main point was that ovulation and menstruation are more or less independent functions in certain fundamental respects. Corner refers to cases in which his monkeys, although menstruating regularly, showed only one corpus luteum between the two ovaries. The author has frequently seen this in the human subject, but usually the menstrual history was uncertain or not obtainable. He has, however, a few cases in which a single young corpus luteum was present in patients who had been menstruating regularly, and Corner refers to similar cases. According to the second theory, the menstrual cycle in the human subject normally proceeds all the year around, but ovulation and corpus luteum formation occur only from time to time. There is no regular date of ovulation, and we are ignorant of its origin. In the absence of fertilization it is probable that several ovulations occur in succession, possibly at monthly intervals, and from each ovary alternately. This would explain why the arrangement of the corpora lutea in series can be made in a large proportion of suitable cases. According to this theory the changes in the ovary and uterus both depend upon the fate of the ovum. Menstruation is a cyclical process which provides for the maintenance of the endometrium in a suitable condition for producing the decidua of pregnancy. The uterus is capable of developing a decidua of conservation whenever it is called upon to receive and nourish a fertilized ovum. In case of failure to implant the ovum or the rejection of the ovum soon after implantation, menstruation would occur from a membrane that could hardly be called anything but early decidua. From a medico-legal viewpoint, however, it would not be justifiable to diagnose the occurrence of pregnancy. Classical decidua or trophoblast must be found. The finding of such membranes in the specimens obtained by curettage for sterility would show that ovulation was occurring and that the prognosis, therefore, was hopeful.—*British Medical Journal*, November 29. 1930. ii. 3647.

LEGAL

CONFIDENTIAL COMMUNICATIONS BETWEEN PHYSICIAN AND PATIENT

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

A physician who had attended a patient in his last illness was requested by the insurance company with whom the deceased held a policy of life insurance to furnish to the company certain information as to the physical condition of the patient prior to his death. The policy was not contested by the company, but it requested the doctor to furnish the information for statistical purposes. The data requested by the company were of such a character, however, that if disclosed they might reflect upon the memory of the patient. The physician was desirous of obtaining the opinion of your counsel as to whether or not he should furnish the information sought. Your counsel, pursuant to a resolution of your Executive Committee, replied to the physician's communication, but since the question is one of general interest to the members of the Society we feel that the matter is worthy of editorial comment in this column.

The statute which prohibits a physician from disclosing information which he acquired in attending a patient in a professional capacity is Section 352 of our Civil Practice Act. This reads as follows:

"*Section 352. Physicians and nurses not to disclose professional information.* A person duly authorized to practice physic or surgery, or a professional or registered nurse, shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity; unless, where the patient is a child under the age of sixteen, the information so acquired indicates that the patient has been the victim or subject of a crime, in which case the physician or nurses may be required to testify fully in relation thereto upon any examination, trial or other proceeding in which the commission of such crime is a subject of inquiry."

What was sought to be accomplished by this statute has been judicially set forth in an opinion written shortly after its enactment. The court said in part:

"It is a just and useful enactment, introduced to give protection to those who were in charge of physicians from the secrets disclosed to enable them properly to prescribe for the diseases of the patient. To open the door to the disclosure of secrets revealed on the sick bed or when consulting a physician would destroy confidence between physician and the patient, and, it is easy to see, might tend very much to prevent the advantages and benefits which flow from this confidential relationship."

The privilege, of course, may be waived by the express act of the patient and there are certain situations where the law implies a waiver. The question of waiver by implication we have discussed in our editorial of October 15th, 1930, and it is unecessary now to repeat what we said in that editorial.

In the question under consideration, there existed between the parties the relationship of physician and patient, and it is also clear that the information sought to be elicited from the physician by the insurance company was acquired by the physician while in attendance upon the deceased in a professional capacity. It therefore follows that the prohibition against disclosure, as set forth in Section 352 of the Civil Practice Act, applies in this case.

In many instances the courts of this State have been called upon to apply the statute under consideration in actions brought by the beneficiary under a life insurance policy, where the company has refused to pay the policy claiming a breach of warranty on the part of the assured. To illustrate our point it is only necessary to consider a typical case, since in that case the court lays down a general principle of law applicable to all similar situations.

In a case decided by our Court of Appeals, the plaintiff's husband was insured by a fraternal organization of which he was a member. Upon his death his widow, as beneficiary under the policy, made demand upon the fraternal organization for payment of the policy. Payment was refused on the ground that the assured had falsely represented in the policy that neither of his parents nor any of his paternal or maternal grandparents nor any of his descendants, so far as he knew, had consumption. The widow then commenced an action against the fraternal organization, and the defendant interposed the affirmative defense of breach of warranty.

At the trial the defendant's counsel, in an endeavor to substantiate the affirmative defense of breach of warranty, offered to prove by the testimony of a physician that he (the physician) had treated for consumption two of the decedent's aunts. The defendant's counsel also offered in evidence the original death certificates of these two persons showing that they died from consumption. The plaintiff's counsel offered the objection that the testimony of the physician, as well as the original death certificates, came within the prohibition of the statute under consideration. The court sustained the objection. On appeal the

defendant's counsel claimed that this constituted reversible error, but the Court of Appeals decided that the lower court was correct in excluding the evidence, and said

It was admitted that the physician had no knowledge on that subject (alluding to the consumption of the insured's aunts) except such as he had acquired in his professional capacity and when the relation of physician and patient existed That testimony of this character is expressly prohibited under Section 834 of the Code (now Section 352 of the Civil Practice Act) cannot be denied That the proof offered and excluded was inadmissible I may assume to be a proposition too clear for argument unless the prohibition referred to has been repealed This court has held that the statements of the attending physician for the purpose of establishing the cause of death either of the insured himself or of his ancestors or their descendants although not parties to nor beneficiaries under the contract were not admissible They are excluded not only for the purpose of protecting parties from the disclosure of information imparted in the confidence which must necessarily exist between physician and patient The disclosure by a physician whether voluntary or involuntary of secrets acquired by him while attending upon a patient in his professional capacity naturally shocks our sense of decency and propriety and this is one reason why the law forbids it The form in which the statements are sought to be introduced is of no consequence whether as a witness on the stand or through the medium of an affidavit or certificate All are equally under the ban of the statute

The question arises as to whether it would be possible for the personal representatives of the decedent, under the circumstances here set forth to waive the privilege so as to permit the physician to disclose the information sought

Section 354 of the Civil Practice Act provides, after setting forth that the privilege obtains unless expressly waived by the patient

But a physician or surgeon or a professional or registered nurse, upon a trial or examination may disclose any information as to the mental or physical condition of a patient who is deceased which he acquired in attending such patient professionally, except confidential communications and such facts as would tend to disgrace the memory of the patient when the provisions of sections three hundred and fifty two have been expressly waived on such trial or examination by the personal representatives of the deceased patient or if the validity of the last will and testament of such deceased patient is in question by the executor or executors named in said will or the surviving husband widow or any heir at law or any of the next of kin of such deceased or any other party in interest

But these provisions do not apply to the question under consideration for two reasons First it will be noted that the statute only contemplates the disclosure of information by a physician as to the mental or physical condition of a patient who is deceased *"upon a trial or examination* secondly, the facts sought to be elicited in the instant case were such as might tend to disgrace the memory of the patient

The disclosure by a physician of information received by him in a professional capacity in violation of the statute already referred to, gives rise to a cause of action in the patient While this right of action is unquestionably a personal right of action similar to an action for libel or slander and hence dies with the patient, the prohibition against disclosure remains, and for the reasons stated the physician may not, under the circumstances here considered, after the death of the patient disclose any information received by him in a professional capacity before the patient's death

CLAIMED NEGLIGENCE IN REMOVAL OF CARTILAGE FROM NOSE

The plaintiff in this case, a mason's apprentice, was employed by a construction company in New York City In the course of his work, he received a fracture of the septum from a piece of brick which had chipped off another brick He was immediately sent to a doctor who, in turn, referred him to the defendant, a specialist handling cases for this particular construction company

The plaintiff complained of marked difficulty in breathing on both sides of his nose, and upon examination the defendant noticed a splinter of bone lying horizontally across both nostrils The defendant advised an operation on the basis of this examination Shortly thereafter, this operation was performed under a general anesthesia by the defendant, a part of the bone spicule having been removed This operation was accomplished by lifting up the mucous membrane, and by the use of approximately a dozen different instruments the bone and cartilage were removed submucously Both nostrils were packed with vaseline gauze

Upon the removal of the spicule bone, it was obvious that a small perforation would result but this condition was passed over because of the relative harmlessness of the perforation as compared with the previous marked difficulty in breathing There was, in fact, no other alternative if the difficulty in breathing were to be remedied by such an operation

The next day the gauze was removed from the patient's nose, and while his condition was reported as very satisfactory, he nevertheless was of a very critical and irritable frame of mind and clearly manifested himself as being thoroughly dissatisfied with the treatment he had received The patient was professionally discharged about a month later, the defendant in the interim having seen and treated the patient at intervals of four or five days The defendant stated that he took in all about one inch of combined bone and

cartilage, leaving about one-eighth inch perforation in the mucous membrane which will be a permanent perforation, and which was the basis for this action.

More than two years later the defendant physician, who had performed what he and his associates considered to be a thoroughly successful operation on the plaintiff, was served with a summons and shortly thereafter a complaint was served in which it was alleged that the defendant did not use due or reasonable care in treating the plaintiff and in endeavoring to cure him of his injury, but that rather because of his lack of professional skill, defendant had caused a hole in the septum between the nostrils, resulting in severe pain to the plaintiff. The answer to all the allegations of negligence on the part of the defendant was a general denial, and an affirmative defense of the Statute of Limitations together with a second defense of payment under the Workmen's Compensation Act in mitigation of damages were interposed.

The plaintiff failed to notice the action for trial and to file a note of issue, with the result that two years later the defendant successfully moved to dismiss the case for plaintiff's failure to prosecute, thus terminating the case in favor of the defendant doctor.

CLAIMED NEGLIGENT TREATMENT OF NEURALGIA

In this case the patient called at the office of a doctor who specializes in surgery and complained of pain in the right leg and hip. He said he had been troubled off and on for about five years.

Upon examination the doctor diagnosed the condition as neuralgia of the sciatic nerve. In order to guard against the possibility of a tumor pressing on the nerve he ordered an *x*-ray taken. In addition, an examination of the plaintiff's tonsils showed them to be badly diseased and he suggested that the patient have them removed. At this calling the doctor prescribed sodium bromide and salicylate by mouth. About a week later the patient returned, having neither obtained the *x*-ray, nor undergone the tonsillectomy. The doctor then recommended diathermy and atrophan by mouth, but gave him none of these treatments.

Several weeks later the patient returned still complaining, and at this time the doctor directed him to go to a hospital for treatment, which he did, and was cared for by a second doctor. This second doctor caused an *x*-ray to be taken, which was negative and demonstrated that there was no objective symptom for the pain in the sciatic nerve. He then injected into the patient's sciatic nerve a solution of 2 c.c. of 5 per cent novocaine immediately followed by 2 c.c. of 85 per cent alcohol. Said injections were made at the lower border of the gluteus-maximus muscle. The patient remained in the hospital but did not improve during the next two weeks and still complained of pain in his hip and leg. The second doctor then decided to perform a Brewer and Lambert operation for stretching the sciatic nerve and the patient consented to undergo such an operation. Under a general anaesthesia an incision was made, about four inches long, down to the sciatic nerve, exposing it at the lower border of the gluteus-maximus muscle. Then, with the fingers of both his hands the doctor grasped the sciatic nerve, raised it up and pulled it in opposite directions, thus stretching the nerve. Next he injected directly into the nerve at the exposed part 2 c.c. of 2 per cent novocaine and 2 c.c. of 85 per cent alcohol. The wound was closed and it healed without any infection or other complications and in about 10 days the patient was taken home from the hospital, apparently still rather lame. Neither of these doctors saw the patient thereafter.

An action was instituted naming both doctors as defendants, claiming that the diagnosis was wrong and the treatment improper. The plaintiff set forth in his complaint that the malady from which he suffered was "zeratic rheumatism" and that the negligent and careless treatment of the patient by the two doctors caused him to be permanently lame and disabled. About three years after the action was started a motion was made to dismiss the cause of action because of the failure on the part of the plaintiff to prosecute the action and the result of this motion was that the plaintiff's attorney consented to discontinue the suit, thereby terminating the matter.

NEWS NOTES

CERTIFICATION OF SPECIALISTS IN GYNECOLOGY AND OBSTETRICS

A movement for the certification of spacialists in gynecology and obstetrics is described in a circular issued by the American Board of Obstetrics and Gynecology which reads as follows·

"The American Board of Obstetrics and Gynecology, composed of nine members and examiners, elected by The American Association of Obstetricians, Gynecologists, and Abdominal Surgeons, The American Gynecological Society, and the Section on Obstetrics, Gynecology, and Abdominal Surgery of The American Medical Association, was formally organized in Niagara Falls, September 16, 1930. The function of the Board is to grant certificates indicating proficiency and specialization in Obstetrics or Gynecology, or both, to those who comply with its requirements.

"The nine members of the Board are:—

Dr. Walter T. Dannreuther, New York City
Dr. Fred L. Adair, Chicago
Dr. E. A. Schumann, Philadelphia
Dr. Paul Titus, Pittsburgh
Dr. Joseph L. Baer, Chicago
Dr. Jennings C. Litzenberg, Minneapolis
Dr. Robert D. Mussey, Rochester, Minn.
Dr. E. D. Plass, Iowa City, Iowa
Dr. G. D. Royston, St. Louis

"This Board has been in the process of organization since 1927. It puts into action a determined effort on the part of these three national organizations to improve the standards of practice of obstetrics and gynecology. It expects to accomplish this by various activities, such as the investigation and encouragement of graduate extension study facilities and active clinical assistantships for men desiring to specialize in these branches; and it will endeavor by regular examinations to determine the competence of specialists in obstetrics and gynecology who apply for the certificate. Certain outstanding specialists will be granted certificates on the basis of their attainments alone, but only by a vote of the entire Board after recommendation by the Committee on Requirements. A second group is asked to undergo a practical clinical examination; whereas a third and younger group has both written and clinical examination and must submit records of a group of cases in order to qualify.

"The national obstetrical and gynecological organizations, which have participated in the formation of the board and are sponsoring its activities, as well as other societies, attach considerable importance to its certificate. It is expected that both the medical and the lay public, including hospital directors, will soon come to utilize the certificate from this board as a means of discriminating between those who are well grounded as specialists in obstetrics and gynecology and those who are not.

"The board does not intend in any way to interfere with or limit the professional activities of any duly licensed physician, but it does aim toward standardized qualifications for specialists in obstetrics and gynecology.

"Any well qualified obstetrician and gynecologist should have no difficulty in obtaining a certificate and the board is desirous of receiving applications from those to whom this applies.

"The first examination for candidates will be held simultaneously in nineteen different cities of this country and Canada on Saturday, March 14, 1931.

"Detailed information and application blanks may be secured from Dr. Paul Titus, Secretary, 1015 Highland Building, Pittsburgh, Penna."

Another circular lists nineteen cities in which the written examinations will be held on March fourteenth. The examinations are described as follows:

"The examination will consist of ten questions on obstetrics and gynecology, and a minimum rating of 75 per cent will be required. Each candidate for Group 3 also will be required to submit typewritten reports on a total of fifty (50) obstetrical and gynecological operations which he has performed, and these case records are to be presented with his examination paper to his local examiner on March 14th.

"The practical, or oral, clinical and laboratory examination will be held in Philadelphia, Pa., on Saturday, June 6th, 1931, commencing at 9 A. M., and will be given to all applicants in group 2 and group 3. The candidates will be expected to identify and discuss three or four common obstetrical and gynecological pathologic specimens and the histologic sections taken from them. The clinical part of the examination will be conducted in a hospital where an individual case will be discussed in detail with each candidate. An endeavor will be made to adapt the details of the oral examination to each candidate's experience and practice, and will be particularly directed to ascertain his familiarity with recent obstetrical and gynecological literature, the breadth of his clinical experience, and his general qualifications as a specialist in obstetrics and gynecology."

The examinations and certifications constitute a step forward in establishing tangible standards for specialists.

NEW YORK STATE HEALTH COMMISSION

This Journal of January first, 1931, page 39, described the organization of the New York State Health Commission appointed by Governor Roosevelt last Spring, and listed the personnel of its fourteen members and the seventy-eight members of its sub-committees. This present article sets forth the scope of the investigations of the Commission, and the general principles of its conclusions:

Immediate Needs: The Commission feels that among the pressing immediate needs are:

1. More effective service in the control of tuberculosis, cancer, and the venereal diseases.
2. Protection of the public health through additional safeguards in the purification of water supplies and the prevention of stream pollution.
3. Better coordination of school hygiene and other health services.
4. More comprehensive measures to reduce infant deaths and deaths among mothers from causes incident to childbirth.
5. Better organization for the discovery, and the cure rehabilitation or care of crippled children.
6. The transcending need, however, which is fundamental to efficient effort in these and all other aspects of public health, is a reorganization of the whole system of local health service on the county, rather than the town and village system, with provision for qualified personnel to conduct all health activities.

County Units of Administration: The Commission has found that in every county of the state there are certain health activities being carried on on a county basis, either a county laboratory, a county tuberculosis hospital, county nursing, or school nursing; and that these elements of health department work could be very wisely coordinated.

The Commission has considered a vast amount of material and discussed a number of problems which exist in many different fields. It recognizes that in the various health activities of the county, the county health board is now essential, and that the organization of the counties should be brought about as rapidly as possible; and that in the larger counties, full-time, qualified health officers should be employed as soon as practicable.

Public Health Nursing: In some counties there is provided by the educational authorities some school nursing service, and other nurses by either tuberculosis authorities or employed by local health departments or voluntary associations without any central supervision. It is recommended that in rural districts the school nursing service be incorporated in the general health program of the county.

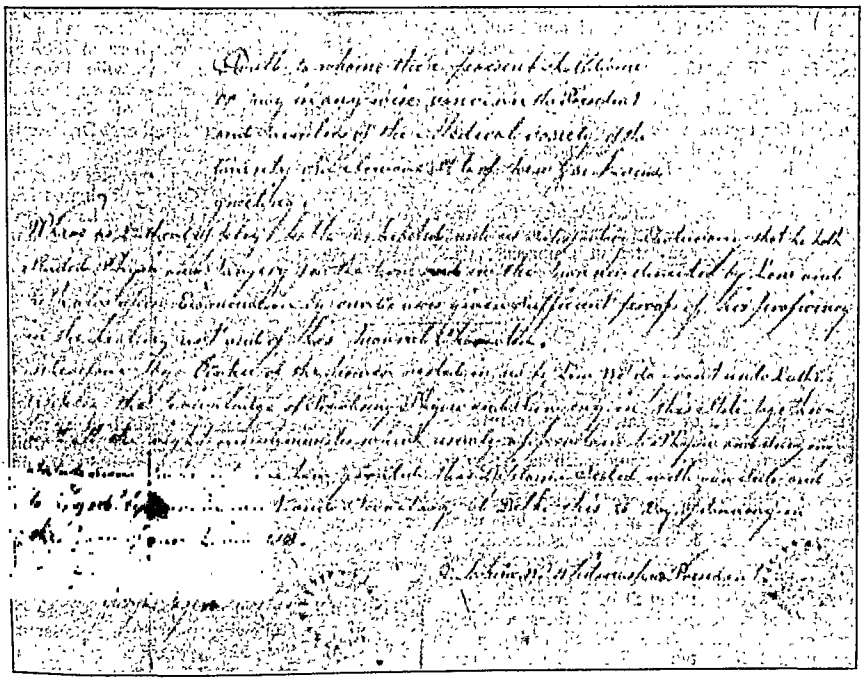
The Commission finds that in some sections a fairly adequate nursing service is provided, but in other sections of the state it is either minimal or does not exist. It believes that there should be a provision of nursing service in those areas which do not now obtain it.

Crippled Children: The Commission has found that there are a large number of children crippled from various causes, and that, in surveys which have been made, a considerable proportion of these children have been found who were not receiving proper treatment. The Commission will undoubtedly recommend that further steps be taken to find these children, and to see that proper medical care is provided for them.

Maternal Mortality: The Commission also notes that while there has been a constant diminution of deaths in infants from preventable causes, there has been little or no reduction in maternal mortality; and this indicates that more serious study should be given by medical and public authorities to the problem of the medical care of mothers, both prenatal and after childbirth.

Cancer Control: The Commission has also commented on the fact that the death rate from cancer has constantly increased, and that some intensive work should be carried on so that more adequate diagnostic service may be rendered and more adequate medical care given to a larger number of patients.

Venereal Diseases and Tuberculosis: The Commission feels that there should be more adequate facilities for the prompt treatment of veneral diseases, and that an additional number of beds are needed for tuberculosis patients which would be more readily accessible to the citizens of the state.



Welfare Law: The Commission also notes that sickness in general creates and increases poverty, cuts down the earning power of the citizens, and increases the cost of their care; and it points out that the newly amended public health law forces welfare officials to provide medical care for persons who, though otherwise self-supporting, cannot provide for the cost of illness.

Sanitation: The Commission has also discussed questions relating to sanitation, and notes that there is still considerable pollution of streams, that water supplies are not fully under state supervision, and that there is still no definite authority for providing sanitary conditions in state parks.

Medical Care: No final discussions have been held on several other topics, and the entire question of medical care has seemed so vast that it has not been possible as yet for the Commission to come to any decision in regard to the question.

DIPLOMA FROM THE DELAWARE COUNTY MEDICAL SOCIETY IN 1813

Dr. Robert Brittain, of Downsville, Delaware County, has sent us the diploma and license to practice medicine which was issued to his great-grandfather, Luther Appley, in 1813, by the Delaware County Medical Society, under the State Law passed April 4, 1806—the First Medical Practice Act in New York State. This license reads as follows:

To all to whome these presents shall Come or may in any wise concern the President and members of the Medical society of the County of Delaware, State of New York, sends greeting.

Where as Luther Appley hath exhibited unto us satisfactory testimony that he hath studied Physic and Surgery for the term and in the manner directed by Law and hath also upon Examination by our Censors given Sufficient proofs of his proficiency in the healing art and of his Morral Character. Wherefore by Virtue of the Power vested in us by Law we do grant unto Luther Appley the privilege of Practising Physic and Surgery in this State together with all rights and immunities which usually appertain to Physic and Surgery.

In testimony whereof we have granted this Diploma Sealed with our Seals and testified by our President and Secretary at Delhi this 28 Day of January in the Year of our Lord 1813.

JOSHUA W. WHITMASH, M.D. *President.*
GEORGE PAGE, M.D. *Secretary.*

Dr. Luther Appley (1) was a physician of considerable prominence. He was born in Canterbury, Connecticut, in 1790, and removed to Delaware County in 1809, where he practiced surveying. He studied medicine with Dr. Lewis Allen, of Deposit, Broome County, and later with Dr. Freeman Allen in Damascus, Wayne County, Pennsylvania. While he received a license from Delaware County in 1813, he also seems to have one from the State of Pennsylvania on November 24, 1821. He practiced medicine in Damascus, and was prominent as an officer in the Pennsylvania Militia. He also practiced in Philadelphia from 1835 to 1842, when he returned to Damascus and practiced there until his death in 1842.

Dr. Luther Appley transmitted his scientific zeal and his love of medical practice to his children's children, for six of his descendants in the succeeding four generations were physicians, two of them—Dr. Robert Brittain and his son, Dr. Knox Brittain—being still in active practice. This is the record number of physicians in any family line in New York State, so far as the facts have come to the knowledge of the editors of this Journal.

Dr. Luther Appley (1) had two sons who practiced medicine. The first son, William Land Appley (2) was born in 1812 in Damascus, Pa., and died in 1877 in Cochecton, Sullivan County, N. Y. He studied medicine with his father and practiced with him, and later in Cochecton. He received the honorary degree of M.D. from the New York State Medical Society in 1858, and in 1867 he was elected a permanent member of the State Society.

The second son of Luther Appley (1) was named Theron (2). He practiced in East Branch, Delaware County, and later in Damascus, Pa., where he died in 1889. He had a son, Otto (3), who graduated from Buffalo University and practiced in Damascus until his death a few years ago.

William Land Appley (2) had a son, William W. Appley (3), and a daughter, Ettie (3).

William W. Appley (3) was born in 1847 and graduated from the Albany Medical College in 1870. He then practiced medicine with his father in Cochecton and continued the practice until his death in 1930.

Ettie Appley (3), sister of William W. Appley (3) married Theron Brittain. They had a son, Robert Brittain (4), who was born in 1867 and now practices medicine in Downsville, Delaware County. He is the physician who supplied the Journal with the photograph of the medical license of his great-grandfather, Dr. Luther Appley (1).

Robert Brittain (4) has a son, Knox Brittain (5), who was born in 1901. He graduated from Cornell Medical School in 1925, and now practices medicine in Spencerport, Monroe County, New York.

HELP FROM WELFARE AGENCIES

Every physician often has occasion to refer a patient to an agency for advice and assistance. There are over one thousand such agencies in Greater New York, whose services are at the disposal of physicians on every conceivable condition, physical, social, and moral; but until recently there has been no central source of information. That defect has been remedied by the establishment of a central clearing house called The Welfare Council of New York City, composed of representatives of all the special and local organizations. The Council maintains a Bureau of Information which is like the Information Department of the Telephone Company.

The address of the Bureau of Information is 151 Fifth Avenue, corner 21st Street, telephone ALgonquin 4-7100. Any doctor desiring information regarding an agency for the care of his patient can obtain it by calling up the Council. If, for example, a doctor has had a chronic patient discharged from Bellevue with the statement that the Hospital can do no more for the case, the physician can call the Information Department of the Welfare Council and get information regarding an agency which will look after his patient. The Council has prepared a booklet listing the more common social problems which every physician meets, and a few of the organizations which are prepared to give help. For example, the first item is headed "Aged—Where to send old people or their relatives to learn about entering a home or securing other care."

The second item is headed "Appeals—Where a doctor can ascertain the standing of a welfare organization appealing for funds."

The conditions listed in the booklet were approved by the following committee representing four of the five county medical societies of Greater New York:

Dr. D. S. Dougherty, New York,
Dr. Alec N. Thomson, Kings,
Dr. E. C. Podvin, Bronx,
Dr. Carl Boettiger, Queens.

Copies of the booklet may be obtained at the headquarters of the county medical societies and from the New York Academy of Medicine or directly from the Welfare Council at 151 Fifth Avenue, New York.

The advisory services of the Information Bureau regarding institutions in Greater New York are available to physicians throughout New York State.

THE GOVERNOR'S ANNUAL MESSAGE

Governor Franklin D. Roosevelt delivered his annual address to the Legislature on the afternoon of Wednesday, January 7, 1931. The paragraphs which are of special interest to physicians are those on Health, Hospitals and Old Age Security.

Health: It was expected that Governor Roosevelt would discuss the subject of health at considerable length, in view of his appointment of the Health Commission whose work is described on page 106. But the Governor wisely confined his remarks to the Committee as follows:

"Last spring I constituted a special committee of citizens and experts, headed by President Farrand of Cornell University, to study a new health program for the State. This is the first time a comprehensive survey has been made since the splendid program sponsored by the late Dr. Biggs. The report of this committee will be transmitted to your honorable bodies at an early date and will, I am certain, mark a very definite advance in the general subject of public health for adults and children."

Hospitals: The Governor discussed Hospitals as follows:

"The overwhelming approval given by the voters of the State in the recent election to the bond issue for erection of hospitals, prisons and other buildings for the care of the wards of the State assures, with the cooperation of the Legislature, the completion of the definite building program outlined by me last year whereby by the year 1935 there will be adequate provision for all patients. It is especially gratifying to note the strides being made by medical science in mental hygiene. The percentage of cures is slowly but constantly rising and at the same time we are making progress in the prevention of mental disorders."

Old Age Security: Physicians desire to insure the comfort of life to all aged persons, and will approve the principles of the remarks of the Governor on Old Age Security:

"In 1929 I recommended to the Legislature a commission to report on old age security against want. The report of this commission resulted in the passage of the Old Age Security bill by the last Legislature, and actual payments under the new law went into effect on January 1 this year. I have many times stated that I am not satisfied with the provisions of this law. Its present form, although objectionable as providing for a gratuity, may be justified only as a means intended to replace to a large extent the existing methods of poorhouse and poorfarm relief. Any great enlargement of the theory of this law would, however, smack of the practices of a dole. Our American aged do not want charity, but rather old age comforts to which they are rightfully entitled by their own thrift and foresight in the form of insurance. It is, therefore, my judgment that the next step to be taken should be based on the theory of insurance by a system of contributions commencing at an early age. In this way all men and women will, on arriving at a period when work is no longer practicable, be assured not merely of a roof overhead and enough food to keep body and soul together, but also enough income to maintain life during the balance of their days, in accordance with the American standard of living.

"The commission which reported last year gathered ample data along these lines on which legislation may be based. I trust that your honorable bodies will give this great subject immediate practical consideration."

LEGISLATION

The Legislature convened on Wednesday, January 7, 1931, for its annual session, and will doubtless consider many bills having medical relations. Dr. Harry Aranow, Chairman of the Committee on Legislation, has anticipated considerable activity this winter, and has sent the following communication to the Chairman of the Legislative Committee of every County Medical Society:

Dear Doctor: January 7, 1931.

The 1931 Legislature has convened and it is exceedingly important that each county committee immediately establish a contact with the Senator and Assemblymen who represent it.

We hope that there won't be any more unfavorable legislation this year than in previous years, but one can never foretell with certainty and so it is highly important that we should build our fences at once. Then, too, we shall have some constructive legislation upon which we hope to get favorable consideration, and this will also call for instruction of your representatives by you.

May I suggest that you call a meeting of the members of your committee and ascertain who the family physicians are to your legislators and arrange to keep them informed up to the minute with the legislative proceedings as they will be reported to you in the bulletins?

I hope that you are making as great use of the bulletins as you can. Some committees meet weekly for a half hour or so and go over the bulletin, making such comments as it calls for; and the chairman reports them to our standing committee. Is it too much to expect that the number of committees taking such a cooperative interest will be greater this year?

Assuring you of my hearty appreciation of the cooperation you can give my committee, I am

Very truly yours,

HARRY ARANOW, *Chairman,*
Committee on Legislation.

SPECIAL COMMITTEE ON PHYSICAL THERAPY

Report to the Council, December 11, 1930

The Special Committee on Physical Therapy reports on its activities during the past month as follows:

1. *Educational:* The Committee endeavored to carry out the recommendation of the House of Delegates that more instruction in physical therapy be given to undergraduates and practicing physicians. It requested the Deans of Medical Schools in New York State to provide facilities for practicing physicians for the observation of the work in physical therapy. The Deans of the Medical Schools of Albany, Rochester and Syracuse signified their willingness to cooperate in this work, and the Dean of the College of Physicians and Surgeons declined to do so.

The Committee again informed all County Societies that, in cooperation with the Committee on Public Health and Medical Education, a postgraduate demonstration course in physical therapy, consisting of four lectures, is being offered, free of charge, to all County Societies; also that the State Committee stands ready to address any County Society on this subject. Requests for such addresses have been received from Essex and Nassau Counties, and arrangements are pending with Erie, Oneida and Schoharie Counties.

In order to discourage lecture courses given under commercial auspices, with their all too evident object of sales propaganda, manufacturers of apparatus were asked to cooperate in the Committee's efforts to foster teaching by medical colleges and by physicians of unquestionable standing. The Westinghouse Electric, General Electric, Liebel-Flarsheim, Burdick and Fischer Companies pledged their support to this policy, and one manufacturer asked for permission to circulate the Committee's statement on The Status of Physical Therapy, nation-wide.

2. *Organization of County Committees:* All County Societies were asked to reappoint special committees on physical therapy, or to appoint new ones where none had been appointed so far. The Counties of Broome, Schoharie, Livingston, Essex and Oneida appointed new committees this year, and seventeen Counties already had a special committee on physical therapy. The members of all of these Committees are being invited regularly to the stated meetings of the State Committee on Physical Therapy.

3. *State-wide Survey of Physical Therapy Activities in Hospitals:* A letter was sent to two hundred and fifty principal hospitals in the State, containing a brief statement about the relation of physical therapy to modern hospital work, and asking information as to whether these hospitals have departments under the control of a qualified physician, and offering the assistance of the Committee in establishing departments and in training physicians. So far almost one hundred and seventy replies have been received, and a good number of hospitals asked further advice. A tabulated analysis of these replies, together with a paper on "Physical Therapy in Institutional Work" will be sent to all hospitals.

4. *Legislative:* The Committee approved a proposal submitted by representatives of the Department of Education for more definite regulations of the practice of licensed physiotherapists.

RICHARD KOVACS, M.D., *Chairman.*

NASSAU COUNTY HOSPITAL

This Journal of November 1, 1930, page 1310, described a campaign to obtain a favorable vote on Election Day on the referendum to establish a general county hospital with special facilities for the care of contagious diseases at a cost of $1,750,000.

The proposition was carried by a vote of eight to one, with a comfortable majority in every election district.

The subject was first discussed by the Society in February, 1922; and was brought before the Board of Supervisors in June of that year; and an extensive report on hospital needs and conditions in Nassau County was given to the Board in December, 1923. The Board, however, took no action, and in 1924 the Medical Society decided to make their appeal to the people. The steps then taken were as follows:

1. The establishment of the *Nassau Medical News* in order to impart monthly news to the physicians and other leaders.

2. A public dinner in Garden City Hotel in December, 1928, at which the need of a hospital was discussed.

3. In January, 1929, a report to the Supervisors was made by Hon. Lewis J. Smith, Judge of the Children's Court, calling attention to the great need of the hospital.

4. In the summer another hospital survey was made.

5. In December, 1929, a two-day Public Health Institute was held under the joint auspices of the County Medical Society and the Red Cross, and was followed with addresses before civic clubs and women's organizations. These organizations joined in a petition to the Board of Supervisors

to appoint a commission to make an official survey of the hospital situation in the county.

7. The Board appointed the commission which reported favorably on a general hospital with two hundred beds, and including a liberal number for contagious diseases. The Board voted to submit the proposition to the voters at the next general election.

8. An active campaign for the proposition was conducted during the summer and fall. This campaign was described in the November issue of the *Nassau Medical News* as follows:

"Gifts of money were received from several public-spirited residents of the county and with the funds thus obtained there was started a campaign of education which resulted in front-page publicity in every paper of the county. More than fifty clubs and organizations were addressed by members of the society; an exhibit was held at the county fair; 65,000 pieces of literature were distributed by mail, by the doctors, the dentists, the druggists, public health nurses and welfare workers; endorsement was secured from prominent people in all walks of life; news releases were sent out to all the newspapers of the county; the representatives of the Metropolitan Life Insurance Company distributed to policy holders literature donated by the company and later, our own leaflets; radio talks were given by the district attorney of the county and by a representative of the society; both major political parties endorsed the movement and instructed their workers to help secure a favorable vote."

The establishment of the hospital has been entirely a Medical Society project, and is an excellent illustration of what a county society can accomplish by persistent action. The present attitude of the Society is indicated in the following paragraph in the *News:*

"Since the hospital has been considered a medical society project, we feel that the overwhelming vote it received is in effect an expression of confidence which amounts to a real responsibility and an obligation to continue our participation in the public health affairs of the county and our interest in the welfare of its people."

SENECA COUNTY

The Fall Meeting of the Seneca County Medical Society was held at the Willard State Hospital on October 9, 1930. At the morning business session Dr. Lester gave an interesting report as delegate to the State Society meeting. He reported that the resolution on the subject of sterilization proposed by the Seneca County Society was "Killed in Committee." Other matters of interest were mentioned comprising a very satisfactory report.

The President, Dr. A. J. Frantz, commenting on the resolution on sterilization, said that he was surprised at the feeble interest shown in it at the Seventh District Branch President's conference and at the State Society meeting. It seemed to him that everyone was very adroitly side-stepping an issue which should be given more careful consideration and hoped that in decades to come there might be something done about it.

Dr. Lester's report was accepted on unanimous motion.

An amendment to the constitution was presented by the following, due notice having been previously rendered to all members: Drs. Lester, Brandt and Gibbs, to-wit: That Chapter IX of the constitution be amended to read that four regular meetings shall be held each year, to occur on the *First Thursday* of the months of June, September, December and March; the March meeting to be the annual meeting.

It was moved on unanimous motion to lay the resolution on the table.

The following officers were elected for 1931:

President—Dr. L. W. Bellows.
Vice-President—Dr. R. F. D. Gibbs.
Secretary-Treasurer—Dr. F. W. Lester.
Delegate to State Society—Dr. W. M. Follette.
Alternate—Dr. E. P. McWayne.
Censors—Drs. F. W. Lester, C. B. Bacon, L. W. Bellows.

The afternoon scientific session was unusual and profitable. Dr. Martin B. Tinker of Ithaca spoke on the subject, "The Advantages and Methods of Use of Electro-Surgery with Special Reference to Goitre and Cancer." A clear description of the improvements in both equipment and technic was given, and the advantages and special indications of this comparatively new apparatus were lucidly described.

The second speaker, Dr. John Wyckoff of New York City, presented the last paper in the series of Post-Graduate lectures furnished by the State Society for Seneca County on Heart Disease. This was a culmination of an interesting series which was well attended. Dr. Wyckoff spoke on the subject, "Syphilitic and Arterio-Sclerotic Heart Disease." This large subject was presented clearly in miniature, and the use of various remedies was discussed in a very comprehensive manner. The paper was exceptionally worth while.

The third speaker was Dr. F. R. Wright of the Clifton Springs Sanitarium who spoke on "Some Thoughts on Diabetes Mellitus." The whole subject of past history of the disease, past dietary fads, present diet conceptions, and insulin was covered briefly but well. The history of insulin was related, and the reasons why various preparations given per os could not have any definite effect on the disease were well delineated.

There was considerable discussion of all the papers and much favorable comment.

ROBERT E. GIBBS, *Secretary.*

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on December 17, 1930, was called to order at 9 P.M., the President, Dr. Gettinger, in the Chair.

The following candidates were elected to membership:

Drs. Arthur M. Freund, Jacob G. Hirsh, Samuel C. Levine, Abraham Lowenbraun, Morris Spindel and Herman Zazeela.

The President referred to charges of unethical advertising which were considered at the last meeting of the Comitia Minora.

The President reported that, at the suggestion of some of the members of the Comitia Minora and others, the chairman of the Committee on Medical Economics and he visited the Emergency Employment Committee, of which Mr. Seward Prosser is chairman. The purpose of the visit was to offer the cooperation of the Bronx County Medical Society. No tangible plan was submitted or has as yet been considered by the Comitia Minora. Dr. Gettinger called for an expression of opinion from the members.

Dr. Podvin stated that, as the President has well said, if the work is done by private agencies, it will be done in a way that will be neither satisfactory to the patients nor to the physicians at large. He expressed the opinion that it would be well within the province of this Society to resolve to offer its cooperation in the matter of medical relief for the unemployed, and to leave the details of the plan to be worked out by the Comitia Minora and whatever organization has this matter in charge. Following the discussion, it was moved and carried that the Bronx County Medical Society go on record as offering its cooperation in the matter of medical relief to the unemployed in this time of economic stress.

Dr. Bick reported for the Social Committee. The beefsteak dinner, with a novel entertainment, will be held at Ebling's Casino on Wednesday evening, January 28th. It will be for physicians only. Members are asked to invite their doctor friends in other counties. The price per ticket is five dollars, and any profit from the affair is to be devoted to the relief fund. Dr. Bick strongly urged the cooperation of the members.

The scientific paper of the evening was on the subject "The Therapeutic Use of Oxygen," by Dr. Alvan L. Barach.

I. J. LANDSMAN, M.D., *Secretary.*

ROCKLAND COUNTY

The annual meeting and banquet of the Rockland County Medical Society was held on Wednesday afternoon, December 3rd, 1930, at 3 P.M., at the Villa Lafayette, Spring Valley, New York. Fifty-five members and guests of the Society were in attendance. Among the guests were: Dr. William D. Johnson, of Batavia, President-elect of the Medical Society of the State of New York; Dr. Daniel S. Dougherty, Secretary of the Medical Society of the State of New York; Dr. Joseph S. Lawrence, Executive Secretary of the Medical Society of the State of New York; Dr. Samuel J. Kopetzky, of New York City, and Dr. Harold Ward, of Englewood, New Jersey.

The Secretary of the County Society reported an active membership of fifty-two, with two retired members. This includes nearly all of the practicing physicians of Rockland County.

The following officers were elected for the coming year:

President—Dr. Leo G. Weishaar, Nanuet
Vice-President—Dr. Stephen R. Monteith, Nyack
Secretary—Dr. William J. Ryan, Pomona
Treasurer—Dr. Dean Miltimore, Nyack

One new member was elected to the Society, and two members were transferred from Suffolk County to the Rockland County Society.

The principal address was given by Dr. W. D. Johnson, on the subject "The Destiny of Man in the Light of His Origin." His discussion was both serious and entertaining.

Dr. Joseph S. Lawrence discussed the subject "The Great Need and Value of a Closer Relationship of the Medical Society of the County with That of the State."

A program of music, entertainment, and good food made the occasion one of gaiety and fun in which the members of the medical profession of Rockland County forgot the cares of medical practice for an afternoon of sociability and enjoyment.

THE DAILY PRESS

COPPER IN THE BODY

The list of metals found in the body is constantly being increased as chemists adopt more and more refined methods of their detection The question is whether the rarer metals are necessary to life and function, or are accidental contaminations. An editorial writer in the New York *Herald Tribune* of December 29 suggests that in either event the body seems to get what it needs. The writer says:

"The work of Dr. F. B. Flinn, of Columbia, on the importance of copper in living matter, mentioned in the recent annual report of Dean William Darrach of the School of Medicine of that university, marks an attempt to make sure of some of the facts underlying observations among the most interesting in modern physiological chemistry. Copper, Dr. Flinn suspects, may be needed in extremely tiny quantities for the operation of bodily organs like the liver or for the proper manufacture of blood.

"The problem of the metallic necessities of living protoplasm is more practical, however, than mere curiosity about which elements happen to be in the human body and how they get there. In primitive times mankind ate so much dirt that any human stomach undoubtedly obtained, in the form of wood, bark, bones, mineral fragments and the like, ample quantities of all metals and probably of all other chemical elements conceivably needed. Nowadays the cult of cleanliness has altered this. On the admirable ground of excluding dangerous germs, all kinds of dirt are kept out of fastidious people's food. This has been known to interfere with sufficient supplies of iron and iodine, as well as of vitamins. Possibly it deprives us also of other elements, like copper or zinc or manganese, which the body needs. That is the importance of investigations like those of Dr. Flinn into the actual needs of living matter for traces of the various metals."

POISON FOG

The newspapers of mid-December carried stories of increased deaths during a period of dense fogs which persisted over northwestern Europe and aroused their greatest fear in the Meuse Valley in Belgium. Commenting on the fears of the people the New York *Herald Tribune* of December 19 has an editorial entitled "Poison Fogs and Foggy Minds," which closes as follows:

"The people of the Meuse Valley are certain that they lived through a poison fog. Every one feels the fascination of their fear and has a vague, subconscious desire to believe in it. Every one likes simple, dramatic explanations of his ills—such as poison fogs and parrot fever. There was psittacosis in the world in the recent parrot scare, but not enough to warrant the slaughter of the pollies. There may well have been poison in a fog in Belgium—certainly the mere suspicion is enough to warrant the most searching investigations—but not enough to justify the poison scares which are inevitable in northern Europe today whenever the gray clouds roll in from the sea. The fact is that despite man's most earnest belief in his rationality he enjoys on occasion the eerie sensation of being scared by something he cannot understand."

OLD AGE PENSIONS

New York State began a system of old age pensions on January first. The proponents of the plan are careful to divest it of the reprehensible terms of charity, dole, and subsidy, as is shown in the following editorial in the New York *Times* of December 22:

"It has been loosely called Old Age Insurance. But it is not that. The design is to give a measure of relief for those who in their later years are unable to support themselves. The work will be done under careful regulation by a State agency.

"The sums thus granted in aid out of State funds will not be a subsidy, a 'dole' or merely a temporary measure of 'relief.' They will be, rather, like the existing system of financial help for widows, a recognition both of service rendered and of the obligation of the community to care for citizens who are no longer able to care for themselves. For them to apply for help is no 'disgrace,' Mr. Folks asserts, when public relief is thus systematically offered and is needed. Moreover, the method may truly be called 'contributory,' since all residents of the State of New York will, directly or indirectly, help meet the cost of the plan through taxation. The results of this fine experiment will be studied with keen interest." (See page 109)

AN AMERICAN HEALER IN INDIA

The New York *Herald Tribune* of December 21 has a half column description of James Brandon, an American from Nashville, who gained a fortune by healing through the use of magic spectacles by which he recognized diseased functions of the body. The article says:

"Brandon was found dead in the squalid cave in which he lived and practiced aceticism, occultism and mystic healing. Since coming to India fifteen years ago he had amassed a fortune by treating the sick, lame, halt and blind with herbs, potions and magic prayers. It was testified at the inquest today that on his deathbed he complained he had lost his occult power because his 'God-given spectacles' had been stolen.

"Witnesses testified that a short time ago some Poona youths, as a practical joke, raided Brandon's abode, stealing all his property, including the spectacles.

"His Hindu friends declare the American recluse achieved many cures. Sufferers of all faiths came to him from many parts of India and he became known as the 'American Buddha.' Outside his darkened abode long lines of broken humanity could be seen daily seeking his supposedly supernatural powers of healing.

"The belief of James Brandon that through his spectacles he was enabled to see God and discover the causes of maladies from which human beings were suffering has a counterpart in the history of Joseph Smith, the founder of Mormonism. At Palmyra, N. Y., a century ago, Smith announced that he had found not only a set of golden plates inscribed with the 'Book of Mormon,' but a pair of crystals set in silver bows —a sort of pair of supernatural spectacles—by the use of which he was able to translate the hieroglyphics on the plates. He called these optical instruments Urim and Thummim, names used in the Bible to describe a method of divination employed by the ancient Hebrews, and believed to have referred to a way of casting lots."

SCIENCE AND RELIGION

The assumed conflict of science and religion has come up in the meeting of the American Association for the Advancement of Science, where the greatest scientists present their latest views on every subject from astronomy to human health. The New York *Times* of December 29, comments on the return of religious faith among scientists, and says:

" 'The intense interest of the moment,' wrote Mr. Gilbert Chesterton in his article in yesterday's *Times* on 'The Return to Religious Faith,' is that the Man of Science has suddenly refused to have anything more to do with 'this dreary business of nibbling negation and blind scratching and scraping away of the very foundations of the mastery of man.' Support for this statement will doubtless appear in the meetings of the American Association for the Advancement of Science beginning today in Cleveland. Five thousand scientists will there represent fifty scientific organizations. More than a thousand papers will be read, each presenting some added word of truth or of opinion or theory based upon research or reason, and all contributing to 'the vision of the plan of things,' which, as Mr. Chesterton remarks, lets us live 'once more in the morning of the world.'

"The president of this scientific federation is the world-famous Dr. Robert Millikan. He has accepted and adopted as his own the estimate that this world has already had a lifetime of at least a billion years and that man has doubtless a billion years ahead of him, with the possibility of learning to live 'a million times more wisely.' We are, indeed, but in the morning of life, and in a world in which science has, to use Dr. Millikan's own words in his book on 'Science and Civilization,' 'laid the foundations for a new and a stupendous advance in man's conception of God, for a sublimer view of the world and of man's place and destiny in it.'

"Here is testimony that the man of science is not engaged in 'nibbling negation' or in 'scraping away the foundations.' Religion is seen by him as the 'integrating factor' in this universe of atoms and ether, of mind and ideas, of duties and intelligence—a religion which grows with the growth of human knowledge. It only enhances the value of Dr. Millikan's affirmation that he was born a minister's son; for he must have known religion 'pure and undefiled' as he has come to know pure science."

The Editorial page of the *Times* of December 31 says further:

"During the past year science has found a new planet; it has conquered a new disease; it has flown to a higher altitude than man had ever before attained; it has verified a thousand years of Biblical history; it has built the highest bridge; it has begun the construction of the highest dam; it has extended the reach of the human voice around the globe and has led man into the conception of the infinite through mathematics. Neither drought nor flood nor financial depression nor any other terrestrial ill can stay the cosmic optimism of the science that not only has such practical application, but that has faith in a continuing creation and that cooperates with 'a Creator continually on the job.' "

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review as dictated by their merits or in the interests of our readers.

BOOK REVIEWS

THE PRACTICAL MEDICINE SERIES. Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Series 1929. Chicago, The Year Book Publishers, 1929. General Medicine. Edited by GEORGE H. WEAVER, M.D., and others. 12mo of 829 pages, *illustrated. Cloth*, $3.00.

This work ranks high in importance. Recent advances of note are ably presented, with the editors' personal opinions upon them. The material is well selected and the editors' opinions are shrewd and concise. The book should be of especial value to the busy practitioner, for quick reference. The format is excellent. Suitable illustrations clarify the text. The sections deal with Infectious Diseases, Diseases of the Chest, Diseases of the Blood and Blood-Making Organs, Diseases of the Kidneys, Heart and Blood Vessels, and Diseases of the Digestive System and Metabolism. A. C. J.

THE NORMAL DIET: A Simple Statement of the Fundamental Principles of Diet for the Mutual Use of Physicians and Patients. By W. D. SANSUM, M.S., M.D. Third revised Edition. 12mo of 134 pages. St. Louis, The C. V. Mosby Co. Cloth, $1.50.

The author presents the fundamental principles underlying the selection of a normal diet in chapters dealing with the bulk requirement of the body, the acid-ash type of acidosis, the acetone type of acidosis, and the caloric, protein, mineral, vitamin, and water requirement of the body. Standard beliefs regarding these matters are well presented except in the chapter dealing with the acid-ash type of acidosis where the views of the writer are given. A list of symptoms is given as due to this type of acidosis and the author thinks that the "blood vessel disease which is responsible for high blood pressure and such complications as partial blindness, heart disease, kidney disease, gangrene and apoplexy," is also due to this condition of acid-ash acidosis. This is certainly an unproven theory, as the author admits.

A number of useful diet menus are given for normal and reducing diets. W. E. McCOLLOM.

A PHYSIOLOGY AND BIOCHEMISTRY OF BACTERIA. By R. E. Buchanan, Ph.D., & Ellis I. Fulmer, Ph.D., vol. 2. Octavo of 709 pages, vol. 3. Octavo of 575 pages. Baltimore, Williams & Wilkins Company, 1930. Cloth, $7.50, each volume.

The Physiology and Biochemistry of *Bacteria*. *Vols.* II and III. by R. E. Buchanan and Ellis I. Fulmer.

"Encyclopedic" is the only word that adequately describes this series of handbooks (Vol. I of which has already been reviewed in this journal). For it has been the object of the authors to present in this work, in systematic fashion, *all* of the worth while material that has been published in this field. In this object they have succeeded admirably. No matter what the needs of the student may be, he can rest assured that he can readily find his topic in the index and then turn to a complete and extensive discussion of that topic.

To give the reader of this review an idea of the scope of these two volumes, the following brief summary of the contents is given:

Volume II. 709 pages in all.

Section A. (25 pages). The recognition and measurement of effects of environment. Highly technical and mathematical; fundamental principles for advanced students.

Section B. (172 pages). Effects of physical environment upon microorganisms. Temperature, various rays and emanations, pressure, surface tension, etc.

Section C. (374 pages). Effects of chemical environment upon microorganisms. Germicides, antiseptics, immune bodies, growth products, etc.

Bibliography for Vol. II, 112 pages.

Volume III. 575 pages in all.

Section D. (30 pages). Symbiosis and antagonism.

Section E (374 pages. Effect of microorganisms on environment, including enzymes and the effect of microorganisms upon both organic and inorganic compounds.

Bibliography for Vol. III, 133 pages.

This valuable work should be available to everyone interested in bacteriology and biochemistry.

ARNOLD H. EGGERTH.

METHODS AND PROBLEMS OF MEDICAL EDUCATION. (Sixteenth Series.) Quarto of 251 pages, illustrated. New York, The Rockefeller Foundation, 1930.

This volume is given over entirely to descriptions, with floor plans and photographs of Departments and Institutes of Anatomy, Histology, and Embryology. Universities of the wide world are represented. Apparently much attention is being paid to plant and equipment. Dr. Lewis H. Weed, detailing a Plan for a Department of Anatomy, has written an excellent introduction.

(Seventeenth Series.) Quarto of 275 pages, illustrated. New York, The Rockefeller Foundation, 1930.

This volume continues the material of the sixteenth series. More Departments of Anatomy, Histology, and Embryology are described, with the same elaborate plan of illustration. An excellent article by Samuel R. Detwiler serves as an introduction. Apparently there is a new science of anatomy. C. A. G.

THE PATHOLOGY OF DIABETES MELLITUS.. By SHIELDS WARREN, M.D., with a foreword by Elliott P. Joslin, M.D. Octavo of 212 pages, illustrated. Philadelphia, Lea & Febiger, 1930. Cloth, $3.75.

Warren considers in this monograph not only the structural changes of the pancreas but also includes the pathology of all the organs involved in the complications or sequelae of diabetes.

He calls attention to the pathological description of the pancreas in diabetes, observed by himself and others. He stresses the fact that a number of these changes are frequently the result of autolytic changes occurring after death. He often observes the same pathological picture in the autopsy material of non-diabetics. His attitude toward the hydropic changes in islet cells, so commonly regarded as the important pathological lesion in long standing diabetes, is a very critical one. Out of 259 pancreases obtained from post mortem examinations of patients previously suffering from diabetes, he was unable to demonstrate any pathological lesion in 27 per cent. A fair number of these were from pre-insulin days. He does not regard with much importance, pancreatic vessel sclerosis as an etiological factor because of its relatively rare incidence in diabetic autopsies. He finds the same lesions just as common in non-diabetics.

There are very good chapters on the role of glycogen and lipoids in diabetes, studied from a histological standpoint.

This book is an excellent compilation of the most recent knowledge of the pathology of diabetes mellitus and is highly recommended by the reviewer.

WILLIAM S. COLLENS.

INTESTINAL TUBERCULOSIS ITS IMPORTANCE DIAGNOSIS AND TREATMENT A Study of the Secondary Ulcerative Type By Lawrason Brown, M D, & Homer L Sampson Second Edition, Thoroughly Revised Octavo of 376 pages, illustrated Philadelphia Lea & Febiger, 1930 Cloth, $4 75

Despite the amount of work that has been done on the subject of Tuberculosis and its complication the belief has continued even from the time of Hippocrates to the present that diarrhoea supervening in pulmonary tuberculosis presaged the early fatal termination of the case

It is really within the past decade, and principally due to the authors of this book that our diagnosis of the intestinal involvement has been placed on a surer foundation, and that our views of its incidence its symptoms other than diarrhoea, its curability and the means of cure have been correctly established

The careful, painstaking work and study reported in the first edition have now been checked in the light of the many criticisms favorable and otherwise which have been made, and the lapsed ten years have afforded opportunities for further study of patients x ray and autopsy records, and of later results in discharged patients

Examination of the gastro intestinal tract by enema of Barium as well as by its oral administration is the essential in diagnosis and as in pulmonary tuberculosis the result of treatment will depend on the time in the disease in which the diagnosis is made The number and quality of the roentgenograms copied in this book make in themselves, an interesting and quite thorough course in the changes taking place in the intestines in tuberculosis In addition, the book contains a wealth of information on the history of this complication, its pathological anatomy physiology clinical findings and the changes in the lungs during its presence.

Above all it brings the cheering news that this complication does not mark the fatal termination but that it is curable that the means of cure in addition to those for pulmonary tuberculosis are medicinal surgical, and Heliotherapy and that in proof of their statements are presented data scientifically obtained warranting acceptance and appreciation T A McG

MANUAL OF PHYSICAL AND CLINICAL DIAGNOSIS By DR OTTO SEIFERT and DR FRIEDRICH MUELLER Authorized translation from the Twenty fourth German Edition by E COWLES ANDRUS M D 12 mo of 543 pages illustrated Philadelphia and London J B Lippincott Company, 1930 Flexible leather $6 00

The above publication will be found to supply just that authoritative information needed by the student intern and physician in his daily ward rounds

We must all feel grateful to Dr Andrus for making available to the American profession this outstanding and most practical work

The volume while made up of 500 pages of printed matter and amply illustrated is yet of pocket size

The volume is a masterpiece for its succinct reliable and practical presentation of methods of examination and for collection of data H M FRIEDMATT

THE WRITING OF MEDICAL PAPERS By MAUD H MELLISH WILSON Third Edition revised 12 mo of 184 pages Philadelphia and London W B Saunders Company 1929 Cloth $1 50

The title of this valuable little handbook does not do justice to its contents It is really a condensed reference book of medical grammatical errors which should be frequently referred to by the general practitioner irrespective of whether he is inclined to do medical writing or not

Contributors to medical literature will find this little volume replete with suggestions helpful in the preparation of papers EMANUEL KRIMSKY

SPINAL ANESTHESIA SUBARACHNOID RADICULAR CONDUCTION BLOCK) Principles and Technique By CHARLES H EVANS M D Octavo of 203 pages, illustrated New York, Paul B Hoeber, Inc, 1929 Cloth, $5 50

The value of a book on Surgical Technique is in part determined by the ability of a novice to acquire from its pages a method that is generally successful and at the same time to avoid pitfalls so common to all surgical procedures In this respect Dr Evans has written a very safe and sane book

Chapter II on the selection of patients for Spinal Anesthesia can be read with profit by all

The Author fails to emphasize the importance of a modified Trendelenberg position immediately after the anesthetic has been injected

The study of physiology and accompanying phenomena is clear and concise

The work of Koster with an experience of many thousands of cases which sets aside many of our pre conceived ideas of spinal anesthesia is not mentioned

Altogether the Author is to be commended for producing a book which is clear but gives the impression that it is the product of his experience minus the knowledge learned by visiting other clinics S L F

COLLECTED PAPERS OF THE MAYO CLINIC AND THE MAYO FOUNDATION Edited by MRS M H MELLISH, RICHARD M HEWITT, B A, M A M D and MILDRED A PARKER B S *Volume XXI 1929 Octavo of 1197* pages illustrated Philadelphia and London W B Saunders Company 1930 Cloth $13 00

For many years the writer has reviewed annually these books the last of which appears as the twenty first volume It contains 1197 pages and has 270 pertinent illustrations The subject matter is as usual so varied that a detailed review is impossible Suffice it to say that there are the original articles or case reports covering every conceivable type of disease This book is highly recommended to the general practitioner and is almost indispensable to the general surgeon M N FOOTE

A TEXT BOOK FOR MIDWIVES By JOHN S FAIRBAIRN M A B M, B Ch (Oxon) Fifth Edition Octavo of 369 pages illustrated London and New York, Oxford University Press 1930 Cloth $8 00

A very comprehensive text book in its fifth edition Physiology bacteriology and anatomy are given much space The preface states that the more advanced school of practicing midwives have an insatiable thirst for knowledge but it is not so in this country A wonderful book for midwives with no possible criticism except the small size of the type Proper assimilation and use of the material in this book would qualify midwives for intelligent management of all the obstetrical emergencies C A G

LEAD POISONING Report of the Committee on Lead Poisoning presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty eighth Annual Meeting at Minneapolis Minn October 4 1929 Octavo of 37 pages New York American Public Health Association 1930 Paper 75c

The report of the Committee on Lead Poisoning of the American Public Health Association presented in pamphlet form is an attempt to set standards for diagnosis individual treatment and industrial control To industrial physicians and others interested in occupational diseases this endeavor to place the real facts as to lead poisoning on a rational basis will be welcome. It will aid in recognizing the early signs of lead absorption it may curb the extremist who thinks contact with lead directly or indirectly is in itself evidence of poisoning A F SHIPLEY

OUR NEIGHBORS

HOUSE OF DELEGATES IN TENNESSEE

The December issue of the Journal of the Tennessee State Medical Association devotes thirty pages to a belated report of the proceedings of the House of Delegates of the State Association, which met in Nashville, April 8-10, 1930, taking the place of the usual scientific articles. The report seems to consist of the stenographic record of everything that was said.

Medical Defense—Regarding medical defense, the report says:

"Last year we reported six non-suits that could be refiled. Two of these have been refiled. These two, with the twenty-two on docket last year made a total of twenty-four suits from last year.

"To January 1st, 1930, we had six suits filed, or a total of thirty-five suits on docket in the ten months.

"One other suit was refused defense on account of the member's failure to pay his defense fee covering the time of the alleged malpractice. Also two threats were referred to the committee.

"As accurately as we can estimate, about seventy per cent of suits are filed on pauper's oath. Every defendant will not report on that point when written for that specific information. (If you write the doctor a questionnaire and ask him a dozen questions, you will do well if you get an answer to a few of them. Why, I don't know. It seems to be in the make-up of the doctor.)

"Perhaps more than fifteen per cent of trials result in non-suit. Less than six per cent of suits result in compromise, and less than two per cent in judgment against the defendant doctor. I don't know whether everybody knows about a non-suit. If you bring up a case and the man can't get all of his witnesses there, as in some cases they can't get a doctor to appear against another doctor, and the judge is about to charge the jury to render a verdict, the man suddenly takes a non-suit. He has a year to refile that suit. Many times they will rehash it again. Things get compromised. We have one suit in one county that has been non-suited four times. The cost of these cases is never less than $40 to the county, sometimes $100, $200, $300 and $500."

Professional Directory: By authority of the Board of Trustees and the House of Delegates a directory in the Journal has been opened to the membership for use. It was our idea that there is a need for such a directory in a state publication; that it will increase the revenue of the Journal to some extent and keep all of its pages allotted to advertising filled.

(The December Journal contains the professional announcements of twenty physicians, listed according to their specialties.)

"The abstracting department continues a popular feature."

Dues and Registration Fees—Regarding dues the report says:

"Our organization is one of the few that carries on activities such as we carry on with membership dues of $4.00 per year. A vast majority of the states have dues of $10.00 per year and upward. Don't misunderstand me now, I am not advocating an increase of dues. I am anticipating our needs and have devised some means by which our increasing financial needs can be met in a logical way without increasing dues. They are as follows:

"1. A registration fee of $2.00 per registrant should be charged at each meeting (of the Association). This fund to go into the treasury of the Association to reimburse in part for money spent in preparation for that meeting.

"2. One-half of the revenue for commercial exhibits goes into the general fund of the Association and the other half into the hands of the local committee on arrangements.

"3. A matter already acted upon by you—the creation of a directory department in the Journal."

There was considerable discussion over the charge for registration at the state meeting. Dr. Taylor said:

"The very men here in town who are too busy to attend these sessions except for the reading of one paper are not going to come here and pay $2 to register. I am personally against that, and I believe every man who considers it rightly is against the proposition of the registration fee. If we have to raise money, let us raise it in some other way."

Dr. Zemp replied:

"I can't agree with Dr. Taylor at all. The medical profession is getting to be like a bunch of preachers. They expect to get everything for nothing. We who attend these meetings and keep up with the medical profession and go around to the various sectional meetings certainly get some benefit from those meetings, and certainly a small registration fee is a very small price to pay for it. I guarantee that the man who stays away from a meeting on account of the $2 registration fee will not come anyhow."

The registration fee was adopted.

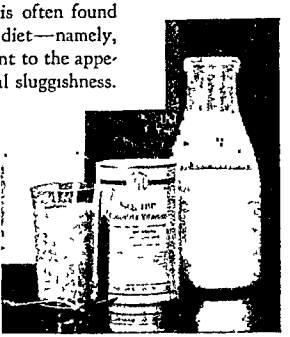
NOW! Squibb provides ADEX TABLETS

A physiologically tested, highly potent and stable vitamin-concentrate of Squibb Cod-Liver Oil.

Cod-Liver Oil has long been recognized as a rich source of both Vitamins A and D, but universal use of the product has been prevented because of its characteristic odor and flavor.

These properties need no longer deprive your patients of these two important vitamins. After a decade of research, the Squibb Biological and Research Laboratories have been successful in developing, from cod-liver oil, a concentrate (Adex Tablets) containing many times as much Vitamin A and Vitamin D as an equal volume of the oil.

One Adex Tablet is equivalent in vitamin content to one-half teaspoonful of Squibb Cod-Liver Oil. Each tablet supplies not less than 1000 U. S P Units of Vitamin A and not less than 48 curative units of Vitamin D. The tablets are prepared under conditions which ensure maximum stability of vitamin content. Marketed in original bottles containing 80 tablets.



NEW! CHOCOLATE-VITAVOSE

For a Delicious, Vitamin-Rich Chocolate Drink by SQUIBB

From a vast amount of research work has come an explanation of the condition known as anorexia, or loss of appetite. It is often found to occur when one important factor is lacking in the diet—namely, Vitamin B. This factor is not only a remarkable stimulant to the appetite, it also aids digestion and helps to correct intestinal sluggishness.

There is now a new, pleasant way to supply Vitamin B in abundance—with Squibb Chocolate-Vitavose, prepared with Vitavose (wheat germ sugar), one of the richest sources of Vitamin B and iron.

Taken in milk, either hot or cold, Squibb Chocolate-Vitavose makes a delicious chocolate drink.

THE "MEDICAL TIMES" AND "LONG ISLAND MEDICAL JOURNAL"

The medical profession of Long Island is homogeneous to a most unusual degree, being isolated by the surrounding water, and every part, even Brooklyn, having developed naturally from individual villages. The unity has been promoted by the Associated Physicians of Long Island, with its eight hundred members and its official organ,—the *Long Island Medical Journal.* Now the Journal, after twenty-four years of existence, is merged with the *Medical Times,* whose managers have come largely from Long Island. The January issue of the combined Journal says editorially:

"As an independent journal the *Medical Times* has won the confidence of twelve thousand individuals; now this confidence is also expressed by a number of bodies representing organized medicine.

"The Associated Physicians of Long Island, now a geographical center of seething activities in the medical sphere, is the fifth organization to register this confidence in one way or another. But in the last case an unusually significant recognition is involved, for the erstwhile organ of the Association, the *Long Island Medical Journal* itself, becomes on January first, 1931, of one flesh with the *Medical Times.* The new publication resulting from this consolidation will be known as the *Medical Times and Long Island Medical Journal.*

"The vigorous life of this young publication—

(*Continued on page* 121—*adv. xiii*)

(*Continued from page 120—Adv. xii*)

its first issue appeared twenty-four years ago has been such as to give a decidedly eugenic aspect to its marriage with the *Medical Times*. The professional progeny of these two trustees of the written word, who will address continents and hemispheres by reason of the far-flung and increased circulation of the new journal, should be a signally significant brood.

"Growth is the law of life. The 'metabolism' of our hospitals, medical schools, societies, medical libraries, clinics and centers is becoming more and more dynamic. Not the least factor making for improved professional metabolism is the sixth —the medical press. That the *Medical Times* has entered the fifty-ninth year of its life better endowed than ever with those elements which enable a publication to compete successfully in a changing world, is due to its adaptability to that world, its readiness to give and take, as shown in the present merger—for realists a significant sign of the times, medically speaking. There is a fine challenge in all this to the forces of organized medicine and independent journalism to go along together in a new way—for extremes to meet, if you like, and the courage that aims at better things to be well tested. The good of medicine itself should be the first, last and only consideration.

"So, in addition to the already great geographical character of the work done by the *Medical Times*, expression will now be given, in the columns of the new journal, to the genius that is germinating and flowering in the colossal medical center of Long Island, that 'Paumanok' beloved of her greatest son, one of America's immortals, Walt Whitman, who so often sang the praises of the 'Sea Beauty! stretch'd and basking!'

"The further destiny of Paumanok looms impressively in the medical scheme of things."

PUBLICITY BUREAU IN INDIANA

The Indiana State Medical Association maintains a Bureau of Publicity of three members who meet regularly. The minutes of the meetings of October 28 and November 11 are recorded in the December Journal of the State Association. They contain approvals of four news releases and provision for speakers for three clubs. They also record answers to questions, as follows:

"The following letter was received by the Bureau:

"'I recently treated the widow of a physician. Her illness resulted in her death. Her husband had been dead for some twenty-five years, and she is survived by two sons and a daughter. She owned some fairly valuable real estate

(*Continued from page 121—adv. xiii*)

"'Should I make a charge for services against the family? I know that I should be somewhat governed by the prevailing local custom but am asking what might be the custom there.'

"The Bureau instructed the secretary to answer along the following lines:

"'The matter of charging for services rendered the patient in question seems to be governed by the personal relations between the physicians and his clientele, local custom, and the physician's own judgment. The Bureau feels that in the abstract there would be no violation of ethics in making a charge under the circumstances mentioned.'

"The following letter was received from a school nurse:

"'Please advise us how far we may venture in advising school children to go directly to an oculist for the care of any eye defects.

"'I am enclosing slips we use to report defects found and of course have had some criticism from the opticians and also one or two family physicians, who feel we should send all cases to them directly.

"'Please give us your statement as to the ethics of this procedure that we may advise our school board, one of whom is a chiropractor's wife, and another who has sent his children to an optician.'

"The Bureau requested the secretary to present this letter to an ophthalmologist asking that he suggest if there is any class of cases which might be referred to an optician or an optometrist and by such action make it possible for a grave condition of the eye to be overlooked. A report of this interview was to be given to the Bureau at its next regular meeting at which time the Bureau will prepare an answer to this question. The secretary was instructed to acknowledge the receipt of this letter and say that the questions would be brought to the attention of the Bureau at the next regular meeting.

"The following letter was received from *American Physicians and Surgeons,* The Midwest Company, Publishers, Minneapolis, Minnesota.

"'An important department in our forthcoming medical directory, *American Physicians and Surgeons,* will be that devoted to health resorts of the better class in every State. We aim to make this of real assistance to those who use the book by listing only resorts to which doctors would refer patients for the treatment of various ailments or for recuperation.

"'We have found it very difficult to obtain reliable information on the various resorts throughout the country, but we trust that you will be in a position to give us advice and assistance in preparing a final list for your State. Enclosed you will find a tentative list which we have prepared. As we wish to include only the

(*Continued on page 123—adv. xv*)

(*Continued from page 122—adv. xiv*)

most reliable and reputable resorts, we would greatly appreciate your advice as to the eligibility of those we have selected, together with any additions to the list you may wish to make.

"'Any information you may give us will be held in the strictest confidence, and we shall be very grateful for your cooperation.'

"The secretary was instructed to answer this letter along the lines indicated by the Bureau of Publicity. This organization has been reported by the Bureau of Investigation of the American Medical Association to be reputable.

"The following letter was received:

"'I have been asked to prepare a paper on Modern Tendencies in Diet and my husband has referred me to you. This paper is to be read before our local Women's Club. I would be happy if you will include some material on the vitamins.'"

The minutes also record several minor facts

PUBLIC RELATIONS COMMITTEE IN PENNSYLVANIA

The December issue of the *Pennsylvania Medical Journal* notices the action of the House of Delegates in establishing a Committee on Public Relations similar to that of the New-York State Society. The Journal says:

"One of the chief topics of critical discussion during the Johnstown sessions of our House of Delegates was the relations existing between the members of the organized medical profession in Pennsylvania and certain health agencies. Several delegates expressed the belief that separate committees should be created to attempt the establishment of more satisfactory relationships with the State Department of Health and with the State Nursing Board. After considerable debate the House decided that the existing Commission to Confer with Private and Governmental Health Agencies should become a permanent or standing committee, and that the subject of coordination between our Society and the State Department of Health should become one of its principal activities.

"Dr. I. H. Alexander, of Pittsburgh, who was reappointed chairman of the commission, is already active and has distributed the subjects referred to his committee to its various members.

"The committee's relation with the Pennsylvania State Dental Society has resulted in the

"The following letter was received from a school nurse:

"'Please advise us how far we may venture in advising school children to go directly to an oculist for the care of any eye defects.

"'I am enclosing slips we use to report defects found and of course have had some criticism from the opticians and also one or two family physicians, who feel we should send all cases to them directly.

"'Please give us your statement as to the ethics of this procedure that we may advise our school board, one of whom is a chiropractor's wife, and another who has sent his children to an optician.'

"The Bureau requested the secretary to present this letter to an ophthalmologist asking that he suggest if there is any class of cases which might be referred to an optician or an optometrist and by such action make it possible for a grave condition of the eye to be overlooked. A report of this interview was to be given to the Bureau at its next regular meeting at which time the Bureau will prepare an answer to this question. The secretary was instructed to acknowledge the receipt of this letter and say that the questions would be brought to the attention of the Bureau at the next regular meeting.

"The following letter was received from *American Physicians and Surgeons,* The Midwest Company, Publishers, Minneapolis, Minnesota.

"'An important department in our forthcoming medical directory, *American Physicians and Surgeons,* will be that devoted to health resorts of the better class in every State. We aim to make this of real assistance to those who use the book by listing only resorts to which doctors would refer patients for the treatment of various ailments or for recuperation.

"'We have found it very difficult to obtain reliable information on the various resorts throughout the country, but we trust that you will be in a position to give us advice and assistance in preparing a final list for your State. Enclosed you will find a tentative list which we have prepared. As we wish to include only the

(*Continued from page 124—adv. xvi*)

"During the past year *Colorado Medicine* has received 65 books for review and 62 volumes of exchange journals. These books and journals become the property of the State Society and are available at the Medical Library in Denver

"The scientific section of the Journal has been ably edited by Dr. J. Rosslyn Earp, to whom the committee extends its thanks and appreciation

"Mr. Harvey Sethman joined the Journal as business manager in October, 1929. His diligence is evidenced by the following potent figures: In the first eight months of the present year the receipts for advertising have been $4,297.28, as contrasted with $2,880.53 for the first eight months of the year preceding, when no business manager was available.

"Another interesting comparison. Advertising receipts for the August issue in 1929 were $250.18. The advertising receipts for August, 1930, were $791.13, an increase of over two hundred per cent.

"For the first time in its history, *Colorado Medicine* is now operating at a profit, and it is to be anticipated that a substantial profit will be shown in the next annual report. The deficit shown in the present report is due to the fact that the advertising increase has benefited only the last five issues of the Journal, while the seven prior issues were run at the customary loss.

"The Committee extends its thanks to Mr Harvey Sethman for his efficient service as Business Manager of *Colorado Medicine*, the official organ of the State Society."

It is interesting to compare this report with that of last year as copied in the NEW YORK STATE JOURNAL of January 15, 1930, page 116.

MEDICAL ECONOMICS IN OKLAHOMA

The December number of the *Journal* of the Oklahoma State Medical Association contains a leading article in which Dr. E. P. Veatch discusses methods of bringing medical service within reach of the indigent in rural sections. Dr. Veatch divides the rural people into four classes:

(1) The well-to-do; (2) The farm owners; (3) Tenant farmers; and (4) Laborers; and continues:

"Under the present social order it is incumbent upon the county commissioner to decide who is sick and who is not. He must decide who is deserving or not deserving. He has never studied medicine a day, he has not studied the problem of the indigent sick. In cases in which he is in doubt or does not wish to decide, he reminds the sick and the physician that he is a member of a

In using lactic acid milk for infant feeding, physicians find Mead's Powdered Non-curdling Lactic Acid Milk No. 1 (containing Dextri-Maltose) the simplest and most satisfactory medium for the preparation of lactic acid milk in the home or hospital. The proper amount of carbohydrate incorporated in this product correlates the lactic acid content, so that it is always ready for use. This product never curdles. Samples and literature sent on request. Mead Johnson & Company Evansville, Ind., U.S.A.

(*Continued from page 125—adv. xvii*)

committee of three and that he cannot decide this. Thus he dodges the issue. He hides behind the other two commissioners and says that nothing can be done and that the first Monday of the month he will take it up with the other two commissioners and see what action can be taken. Neither the patient, the community, or the physician can put off this illness until the commissioners have time to meet and consider the merits of the case. In most cases when he wants a road or bridge built he hires an engineer. When he wants a public building constructed he hires an architect, but when it comes to passing upon a medical problem he considers himself thoroughly competent to pass on these conditions; and should he decide unfavorably, asks the neighbors to take care of the patients themselves or raise some money among the friends to pay for this service.

"The average fee paid by the county commissioners for hospital care is $15 a week on cases they approve. In the main no arrangement is made for the indigent sick outside of the hospital. That is at the expense of the country physician. These are taken care of usually in private hospitals at a loss.

"The problem of curative medicine with the people in class three or four must be met in one of two ways; first, a full time County Physician on a salary to look after this class of patients; second, an agreement with the physicians already practicing in the county to be paid for the actual expense of the care of this type of patient. It depends on the community as to which plan is the better. It is unfair to a physician to spend his time with patients who never can pay. He loses much of the better class of work if he does this. The public and the commissioners must be educated to the fact that the indigent sick is a social problem and should be taken care of through the regular channels of the county.

"This type of rural folk in class three and four are really deserving and will make American citizens if given a chance. Money invested in citizenship will surely bring in its return as much as money invested in public improvements. We have the idea it is right to spend all the money the county has to fix a mud hole in front of a man's house, but none whatever to care for the man within the house who is sick and has no credit, no money, and no way of receiving or paying for medical aid."

"The author believes that this is the solution. The county health office should be given the authority to pass on the physical condition of the patient, and an assistant be furnished to give the social and financial rating. This is how it would work. A physician sees a patient who never will be able to pay. He notifies the health office. This office immediately investigates and reports the

(*Continued on page 127—adv. xix*)

(*Continued from page 126—adv. xviii*)

case to the commissioners, with an opinion concerning the physical and financial condition. With these reports and that of the resident physician, they would have sufficient facts upon which to decide the merits of the case. This is the plan by which the indigent sick of the rural communities can receive proper medical attention and the physician be treated justly and with equality to all."

LEGISLATION IN WEST VIRGINIA

The January issue of the *West Virginia Medical Journal* contains the following presidential comments on educating legislators by Dr. C H. Maxwell:

"This is the President's Page I am proud of it. I hope to keep up its prestige, interest, and worth. The universal expression of loyal support of our Association makes one enter on his duties with a sense of the grave responsibility to the medical profession and the general public.

"We have been accused of being remiss in our duty to the general public, especially in preventing vicious or unnecessary legislation. We appoint a legislative committee and tell it to do the work. I felt that we should get closer to the ones in authority, so I sent a circular letter to each candidate for the legislature before the election, knowing that each one would read it in the quiet of his home and learn that the medical profession was ready to assist in having good laws passed Since the election I have sent the following to each member of the House and Senate:

"As a member of our legislature you will soon meet the other members in Charleston, and you will be called upon to assist in sifting the good bills from the bad ones. The doctors of the state have been accused of not doing their duty in helping to prevent legislation not to the best interests in the general public. This lack of cooperation has been due to their devotion of the welfare of their own immediate surroundings and they have not felt that their influence for good should extend to the entire state. But recently they have been aroused to the fact that they owe a duty state-wide in its scope.

"It would be well if the members of our legislature would consult their family physicians and the doctors in the legislature on all matters of public welfare and get their views in such matters. These views, in the main, would be correct, and be an aid to the legisla-

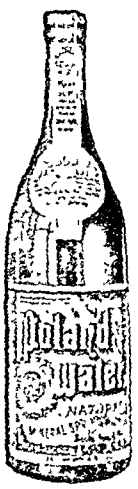
THE WISCONSIN MEDICAL JOURNAL

The November number of the *Wisconsin Medical Journal* contains a report of the meeting of the House of Delegates held September 9th to 11th, in Milwaukee. The Editorial Board discussing new plans for the State Journal reported:

"During 1929, Dr. Doege, then President of the State Medical Society, presented to the Council a program which had as its chief ideal and aim the improvement of the quality of the scientific work done by Wisconsin physicians and surgeons. The basis of Dr. Doege's plan was the employment of a very high grade of physician who was, in the first place, to act as medical editor of the Journal. In the second place, Dr. Doege's idea was to have this man stimulate medical practice and thought of Wisconsin physicians through articles in the Journal, through personal contact, and by any other means available. As this proposal involved an expenditure of between ten and fifteen thousand dollars, it was considered out of reach of the State Medical Society's finances at that time."

The Board considered three plans: 1, a full-time editor-in-chief; or 2, a part-time head of the Journal; or 3, an unpaid editorial staff, as at present. But the Board reported that it had published an appeal to the members to write their opinions to the editor, and the response was one lone letter, concerning which the editor reported:

"As a result of that editorial, we have one letter of criticism, a very good one and very much to the point, a very much worth while criticism, and yet it is the first letter of criticism that we have had in a number of years, how many I do not know."



The employment of a full-time editor is dependent on an increase in the annual dues of the State Society. (See N. Y. STATE JOURNAL OF MEDICINE, March 1, 1930, page 302).

NEW MEDICAL SCHOOL IN LOUISIANA

The January issue of the *New Orleans Medical and Surgical Journal* contains the following announcement of a new medical school in connection with the Louisiana State University:

"Governor Long in his announcement said that the first two years will be conducted at Baton Rouge; the last two years will be in New Orleans in the Charity Hospital. The general plan is that the new school will start to function next fall. There will be required of the students a year's service as an interne before receiving their degree. The Charity Hospital will have ample space not only for the new school but also for the Tulane Medical School. The Governor announces that it is his plan to give to the prospective medical students of Louisiana an education, which will be within their financial resources and which will increase the number of physicians practicing in the State, more particularly in the country districts. The new school will be a splendid addition to the medical activities of the State, and should be welcomed by everyone in the profession."

GRIEVANCE COMMITTEE IN WASHINGTON

The House of Delegates of the Washington State Medical Association, meeting on September 2, passed the following resolution:

"In the matter of a Grievance Committee, we recommend that, in view of the fact that the subject is too large to be decided hastily, it be referred to the Board of Trustees of this association and the Executive Committee of the Public Health League, with instructions to consider this question in all its angles, secure such legal advice as may be deemed necessary, and report their findings and recommendations to the House of Delegates at the 1931 session of the Washington State Medical Association.

"This resolution was adopted."

PULMONARY COMPLICATIONS IN SURGERY OF THE HANDICAPPED PATIENT*

By EDGAR W. PHILLIPS, M.D., ROCHESTER, N. Y.

From the Department of Surgery, The University of Rochester School of Medicine and Dentistry.

THERE has been, during the past few years, a growing tendency to study the end results in surgery. The need of such a step was well expressed by Cutler and Morton[1] when they wrote "Taking our mishaps one by one, they are soon forgotten and we may be led to believe that our results are better than they appear in cold figures." A study of the many statistics published upon the incidence of postoperative pulmonary complications warns us that these dangers should receive careful consideration when an operation is being advised. The lack of carefully weighing the benefits to be derived from an operation with the dangers incident to it, combined with the often very casual preoperative examination of the patient, has resulted in tragedies distressing to the patient and to the surgeon.

The collected figures of the incidence of postoperative pulmonary complications cover operations performed upon all types of patients. There is no special group of complications which are peculiar to the so-called handicapped patients; these patients differ from the average surgical cases only in that they have an increased incidence of all of the possible pulmonary complications and an increased mortality percentage of the morbidity. In an analysis of the literature up to 1921, Cutler and Scott[2] collected statistics of about 100,000 cases. In this large group, the pulmonary morbidity, following operation, varied from 1.2 per cent to 3.9 per cent. These authors feel that the percentage of pulmonary complications, following operations, is close to 3 per cent of all cases operated upon. With the improved methods of diagnosis and the increased interest in this subject, there seems to be little doubt that a larger percentage of these complications is being discovered. Coryllos[3] says that there is some degree of collapse of the lung in at least 10 per cent of all patients after surgical operations. It seems quite likely that, in the older statistics, many of these less marked changes were overlooked. The percentage of pulmonary complications, following operations upon the abdomen, is very definitely increased over operations upon the extremities. Boland and Sheret[4] state that 13.7 per cent of all abdominal operations are followed by pulmonary complications. The morbidity percentage is further increased in operations upon the upper abdomen. At the Lakeside Hospital, Studley[5] found postoperative pulmonary complications in 13.7 per cent of patients having upper abdominal operations. The mortality of these complications has been recorded as high as 58 per cent.

The various types of postoperative pulmonary complications are: acute bronchitis; bronchopneumonia and lobar pneumonia; massive atelectasis; pleurisy; lung abscess; empyema; thrombo-embolic disease; pneumothorax and the activation of a latent focus of pulmonary tuberculosis.

(a) Acute Bronchitis.—This condition is very likely to make miserable the postoperative convalescence of patients operated upon during a season in which acute respiratory infections are prevalent. This is especially true if the patient is operated upon during his convalescence from such an infection. The symptoms usually begin within twenty-four to forty-eight hours after operation. There is severe cough, with profuse expectoration; the patient is apt to be somewhat cyanotic and many rales are found upon examination of the chest. The prognosis generally is considered good and the presence of this com-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

plication has not been considered serious. However, if time should prove that the interesting theories advanced by Coryllos and Birnbaum[6] are true, the presence of this complication may be regarded with apprehension. They think that the postoperative complications in the pulmonary parenchyma may have a common pathogenesis and that they are secondary to bronchial obstruction. The increased secretion incident to acute bronchitis may play a part in the subsequent development of more serious complications—either pneumonia or atelectasis.

(b) Pneumonia.—Whether the theory of aspiration; the embolic theory or the theory of bronchial obstruction will finally be accepted as the etiological factor in postoperative pneumonia, is rather unimportant. The main consideration is that we have done away with the term "ether pneumonia"; it has been found that the incidence of pulmonary morbidity is as great in patients operated upon with gas-oxygen anesthesia or with local anesthesia. Bronchopneumonia is a more common complication than the lobar type. Cutler and Scott,[2] in a collection of 31,368 cases operated upon in general surgery, found that 1.12 per cent developed pneumonia and of these, 46.1 per cent died. This mortality rate is well above that of the medical pneumonias except those occurring in the physically infirm. These postoperative pneumonias are generally caused by the saprophytic Group IV pneumococcus which organism is present in the upper respiratory tract of over 50 per cent of normal individuals. It is surprising that this pneumococcus of low toxicity should cause so high a mortality in postoperative pneumonias.

(c) Massive Atelectasis.—Much confusion still exists in the use of terms describing this condition. If we are to call the airlessness of a lung "massive atelectasis," the term should be reserved for that group of cases in which the pathogenesis is not some form of compression. Coryllos and Birnbaum[7] have suggested the name "obstructive massive apneumatosis of the lung." This seems descriptive and differentiates the condition from the atelectasis produced by compression.

A large amount of clinical observation and experimental work, upon this subject, has appeared in the literature during the past ten years. Time does not permit more than a brief discussion of this interesting problem. There have been several theories advanced to explain the etiology and these may be divided into three classes: (1) Decreased respiratory motion. (Pasteur attributed atelectasis to paralysis of the diaphragm. Bradford thought that an atelectasis, following wounds of the chest wall, was due to immobilization and retraction on that side of the chest). (2) Bronchial obstruction. The majority of those writing upon this subject feel that obstruction some place in the bronchial tree is necessary for the production of atelectasis. This obstruction is described by some as a reflex contraction of the bronchial muscles and, by others, as a mucosal swelling, but the majority have considered it to be due to plugging of the bronchi with mucus. (3) Some investigators have suggested that the origin of the disease lies in a vasometer reflex to which is later added plugging, by secretion, in some part of the bronchial tree.

Irrespective of what the original etiological factor is, everyone agrees that atelectasis cannot occur without complete obstruction some place in the air passages leading to the involved lung. It is also equally true that this condition is most commonly a postoperative complication in patients who have been subjected to abdominal operations. These patients have hypoventilation and Churchill and McNeil[8] have shown that the limitation of respiratory excursion leaves the patient with but 25 to 50 per cent of his preoperative vital capacity. This hypoventilation is the result of splinting of the abdominal and thoracic muscles, because of pain; abdominal distention; the use of a tight abdominal binder and the use of morphine for the control of pain during the immediate postoperative period.

The extent of atelectasis varies from the small, patchy involvement to a condition in which all the lobes of one side are rendered airless. In the marked forms, the symptoms are characteristic and the diagnosis is readily made if one is familiar with the picture. However, before Pasteur's rediscovery of the condition, it was commonly called pneumonia. The milder forms of lobular or patchy atelectasis are frequently overlooked. The symptoms vary according to the degree of involvement. In the massive forms of atelectasis, there occurs, usually within the first two or three days following operation, a feeling of tightness in the chest, accompanied by cough and expectoration, and the usual evidence of mild infection as expressed by temperature and pulse elevation. Examination of the patient reveals a characteristic picture: There is retraction and immobilization of the affected side of the chest, with narrowing of the interspaces, and retraction of the heart towards the side of the disease. Upon *x*-ray examination, there is obliteration of the lung field by a shadow and evidence of a raised diaphragm on the diseased side, together with cardiac displacement toward the involved side. The minor forms of atelectasis are quite likely to be missed as the symptoms and signs are not

marked and the condition is apt to be of short duration.

The observation of patients, who have started in with the characteristic symptoms of the initial period of an atelectasis but who have been spontaneously relieved of these symptoms, makes me feel that there is an abortive form of atelectasis. This was strikingly illustrated in the case of one patient who stated that his symptoms of about twelve hours' duration were suddenly relieved by a coughing spell during which he had the sensation of something breaking loose in his chest.

(d) Pleurisy.—Pain of pleuritic origin is usually the result of a small area of infarction from a sterile embolic process which lodges in the distal lung capillaries. It may be the forerunner of multiple emboli in the smaller vessels, or possibly of a fatal pulmonary artery blockage. Pleurisy, either wet or dry, may also be associated with postoperative pneumonia and, more rarely, is the result of the activation of a latent focus of pulmonary tuberculosis.

(e) Lung abscess.—Operations upon the nose or throat contribute many cases of lung suppuration. However, in any large series of lung abscesses, there will be found incidences in which this complication follows operations in other regions of the body. It may be the result of the breaking down of a postoperative bronchopneumonia, or an area of infarction, when the embolus producing the infarction comes from an infected field. The physical signs and symptoms of a lung abscess are so well known that they will not be discussed here.

(f) Empyema.—Infection of the pleural cavity is not a common postoperative complication. It may follow a postoperative pneumonia or a lung abscess. In addition to the cases originating from intrapulmonary lesions, infection may extend through the diaphragm from subphrenic collections of pus.

(g) Thrombo-embolic Disease.—It should be emphasized that embolism of the lungs is more of an incident to the postoperative period than a complication of the operation. Meyer[9] says that in the municipal hospital at Charlottenburg-Westend, where there is a surgical service of five hundred beds, no case of embolism of the lung occurred on this service in a period of one month while, during the same period, with the same number of beds, the medical service lost seven patients with pulmonary embolism.

The pathology of thrombo-embolic disease is not understood. Thrombotic processes in the prostatic and pelvic plexuses and in the femoral veins, are the common sources of emboli. The present knowledge of thrombus formation, which ascribes clotting within the vessels to changes in the blood constituents, rate of flow of the blood stream and changes taking place in the vessel walls, seems insufficient to explain the process. According to Walters,[10] physiological changes and adjustments, which follow surgical procedures, seem to be concerned in the formation of postoperative pulmonary emboli. These changes, he feels, are the result of a decrease in metabolic activities; a tendency towards a decrease in the rate of blood flow, with a decrease in blood pressure and changes in the cellular constituents of the blood.

Pulmonary infarction usually occurs a number of days after operation. The emboli are multiple and are most commonly located in the lower lobes. In non-fatal pulmonary embolism, there is often a very abrupt onset of dyspnoea; pain in the chest; cough and sputum containing a small amount of blood. Fever is often absent. The *x*-ray reveals a wedge-shaped shadow with its base at the lung periphery. There are all grades in the severity of the symptoms, from the mild case which resolves, without any residuum, in a few days, to a plugging of the pulmonary arterial system of so great an extent that death is almost immediate.

One of the greatest tragedies occurring in medicine is that of a fatal pulmonary embolism. As a postoperative complication, it generally occurs from seven to fourteen days after operation, at a time when the family and the surgeon feel that the patient has made a satisfactory recovery. At times, there are premonitory warnings, caused by showers of small emboli, but, frequently, the disaster comes suddenly. The patient may cry out with pain and the facial expression is that of great anguish. Extreme dyspnoea, with marked cyanosis, follows and the patient may die almost immediately. Sometimes the fatal outcome is delayed for a great many hours. Lord[11] in discussing a paper by Nystrum of Sweden, read before the annual meeting of the American Surgical Association on May 17th, 1930, said that of the 60 cases of fatal pulmonary embolism that he had studied, only 18 lived for ten minutes or over. In these suddenly fatal cases, the embolus is usually large and is situated at the bifurcation of the pulmonary artery, extending into both branches and practically occluding them.

(h) Pneumothorax.—Spontaneous pneumothorax as a postoperative pulmonary complication is rarely observed in operations that do not open the thorax. I have seen but one example of this complication and this occurred following a gastro-enterostomy performed because of obstruction, from carcinoma, in the third portion of the duodenum. The symptoms, physical signs and *x*-ray picture are characteristic and need not be discussed here.

(i) Activation of a Latent Focus of Pulmonary Tuberculosis.—Operations performed upon patients with a latent focus of pulmonary tuberculosis may cause an activation of the process and precipitate a downward course, eventuating in the death of the patient. Unrecognized active tuberculous lesions in the lung may also spread more rapidly as a result of anesthesia and the debility following an operative procedure. It is imperative that careful chest examinations be made, before a patient is submitted to an operation, in order that this complication may be prevented.

Prevention and Treatment of Postoperative Pulmonary Morbidity.—Most operations, today, are of the elective type and safety should not be sacrificed to hasten the procedure. The better the patient's general condition when he comes to the operating room, the fewer will be the postoperative complications. Surgical enthusiasm must be held in restraint in the presence of upper respiratory infections. The chest examination should be thorough in order to rule out bronchitis and tuberculosis. Those patients with myocardial weakness will be benefited by a period of rest and digitalization.

Hyperventilation, at the conclusion of the operation and repeated during the early postoperative hours, upon the appearance of symptoms suggesting pulmonary involvement, will lower the incidence of lung morbidity. Graham[12] says that all that is necessary to prevent massive atelectasis is to insure a proper inflation of the lungs. In the surgical clinic of the University of Rochester Medical School, hyperventilation, with carbon dioxide, has been used, at the suggestion of Dr. W. J. M. Scott, for four and one-half years and no case of atelectasis has developed in a patient receiving hyperventilation. The value of this type of hyperventilation has been proven by Henderson and Haggard[13]; using it for the treatment of carbon monoxide asphyxia, they discovered a notable decrease of postasphyxial pneumonia. Henderson, Haggard, Coryllos and Birnbaum[3] believe that apneumatosis is prevented and relieved, and the risk of pneumonia eliminated, by the inhalation of carbon dioxide.

Inhalation of carbon dioxide and oxygen causes the most active hyperventilation, However, increased distention of the lung may be brought about by encouraging coughing and deep breathing; the sparing use of opiates; the turning of the patient from side to side and by the struggling incident to the passage of a bronchoscope.

Prevention of Embolic Disease.—There is, apparently, very little that can be done to prevent thrombo-embolic disease. Walters[10] advises the use of desiccated thyroid gland tablets, in doses of two grains, in order to combat the decreased metabolism. He also encourages patients to move about in bed and flex their arms and legs and turn from side to side. Since following out this treatment in a group of 4,500 cases having had major surgical procedures, there was an incidence of fatal pulmonary embolism in less than 0.09 per cent. In a larger series of cases between 1917 and 1927, the incidence of fatal postoperative embolism was 0.34 per cent.

In Germany and the Scandinavian countries, many attempts have been made to remove the emboli from the pulmonary arteries. Trendelenburg, in 1908, first proposed this procedure but it was not until 1924 that Kirschner saved the first patient by this heroic operation. Since then two recoveries have been credited to Meyer[9]; two to Nystrum and two to Crawfoord in Giertz's Clinic. In patients, with massive pulmonary embolism, who live for at least ten minutes and who can, definitely, be said to be dying, this operation seems justified.

SURGERY OF THE HANDICAPPED PATIENT: THE CHOICE OF THE ANESTHETIC*

By W. J. MERLE SCOTT, M.D., ROCHESTER, N. Y.

From the Department of Surgery, the University of Rochester, School of Medicine and Dentistry.

USUALLY the choice of an anesthetic is a matter of personal preference and convenience to the surgeon and patient. In most operations of election it is unimportant in regard to the ultimate outcome whether a general, a spinal or a regional infiltration anesthesia be employed. Each surgeon has his personal preferences and most of us tend to become routinists in this matter. In the group of handicapped patients, however, the choice of the anesthetic becomes a matter of progressive importance as the degree of the handicap increases. Operations of election in such individuals can of course be postponed or denied to the patient. Operations of urgency or necessity, however, must be carried out. Consequently it is incumbent upon us, by the choice of our anesthetic, to diminish the harmful effect of the handicap as much as possible, or at least not to increase it more than necessary.

Fifteen years ago the number of anesthetic agents from which to choose was decidedly limited. In this country ether was used with few exceptions, though nitrous oxide-oxygen and local anesthesia were skillfully employed by a minority. In the last decade, however, we have made very considerable advance with our anesthetic agents. New ones such as ethylene, avertin, and sodium amytal have been added for clinical use and valuable improvements have been made in the administration of the previous ones, particularly in connection with the advantageous use of carbon dioxide during and at the end of inhalation anesthetics and with improvements in spinal anesthesia.

The perfect anesthetic has not yet been found. Such an agent should produce entire absence of disagreeable sensations for the patient combined with complete muscular relaxation without any immediate or late deleterious effects. Each of the anesthetics to be considered aproaches this ideal in some ways more closely than in others, so that each has its particular advantages complicated by its own disadvantages. As the handicaps vary greatly in their characteristics, it is necessary in each instance to pick that anesthetic which is best adapted to the individual situation. It seems advisable, therefore, to consider briefly the advantages and disadvantages of each one.

CHOICE OF ANESTHETIC

	Advantages	*Disadvantages*
Ether	Universal Applicability Relaxation Large Margin of Safety	Metabolic Changes Pulmonary Irritation
NO_2O_2	Rapid Recovery Minimum Metabolic Changes	Poor Relaxation Venous Congestion
Ethylene	Advantages of NO_2O_2 Better Relaxation	Explosibility Relaxation Incomplete
Spinal	Muscular Relaxation Contracted Intestine	Irreversible Drop in Blood Pressure Rare Nerve Injury
Basal	Loss of Mental Trauma Less Postoperative Discomfort No Venous Congestion	Irreversible Hypersensitivity
Local	Minimum Trauma and Metabolic Changes	Time and Space Limitations

Discussion of Anesthetic Agents

Ether produces in general a very satisfactory anesthetic with good relaxation. Its chief drawbacks consist in metabolic changes and post-operative discomfort. In high concentration it may produce pulmonary irritation, though this factor has certainly been over-emphasized. Nitrous oxide-oxygen is superior to ether in the speed with which induction can be comfortably completed and the rapid recovery of consciousness after operation. In a well carried out anesthetic there are very few metabolic changes. The chief defects consist in poor relaxation, venous congestion and a tendency to an increase in blood pressure. Ethylene has the advantages outlined for nitrous oxide-oxygen added to which there is better relaxation of muscle spasm. Against its usefulness is its explosibility and the fact that relaxation with it is not ordinarily as complete as with ether. There is no doubt that the explosive hazard of ethylene is slight when proper precautions are taken. This has recently been the subject of a report by a special committee of the American Medical Association to study anesthesia accidents. Spinal anesthesia had for many years been used for a limited group of patients, particularly in amputations of the leg for arteriosclerotic or diabetic gangrene. The more recent applica-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

tion of ephedrin to stabilize the blood pressure and a better understanding of the mechanism of its serious reactions greatly increased the field of usefulness of this anesthetic. Its particular advantages consist in muscular relaxation and contracted intestines. Its disadvantages are its irreversibility, the depression of blood pressure, and rare nerve injuries that occur with it. While it is usually a most satisfactory anesthetic, it still has a greater hazard from serious accidental sequelæ than the inhalation anesthetics. This danger is slight and is not to be thought of where the advantages of this particular form of anesthetic outweigh them. For example, it is almost always my anesthetic of choice for cholecystectomy. The muscular relaxation and the ease with which the abdominal contents can be excluded from the field more than outweigh this very slight risk. However, in the usual, uncomplicated, inguinal hernia without obesity, it seems to me that its routine employment in place of local or inhalation anesthesia is undesirable. The basal anesthetics, avertin and sodium amytal have been introduced in the last five years. At first, the attempt was made to employ them as the sole anesthetic agent. This was followed in both cases however by unfortunate results due to the varying effects of the substance upon different individuals. With such doses, patients recovering from amytal have a prolonged excitement period. With avertin used in these doses several fatalities occurred. In both cases then the dose has been reduced and a basal anesthetic is induced which occasionally is sufficient alone but usually has to be augmented by either local or inhalation anesthesia. The advantage of such a procedure is the loss of mental trauma, lessening of postoperative discomfort, and from the technical standpoint, the absence of venous congestion when nitrous oxide-oxygen is used as the supplement. With each of these basal anesthetics the patients go to sleep but the depth of the sleep varies with each person. The disadvantages consist in the irreversibility of the action and the individual differences in effect. Used as basal anesthetics, however, both of them seem safe and possess very real advantages in certain cases. Much more extensive clinical trial will be necessary before the comparative advantages between these two can be stated. Sodium amytal is given intravenously and ordinarily is associated with practically no fall in blood pressure but does seem to depress the respiratory reflexes more than avertin. The latter is given by rectum. Its solution must be carefully tested by a simple procedure before administration, as any decomposition causes the formation of a substance irritative to the rectal mucosa. While avertin is ordinarily associated with a drop in blood pressure of 20-30 mm., it rarely requires even the administration of ephedrin to peg this. Also the addition of nitrous oxide-oxygen usually rapidly raises the pressure if it does drop. This sequence, avertin followed by nitrous oxide-oxygen, has in our hands given very satisfactory results. Barbituric compounds in large doses have been given by mouth for basal anesthesia, but we have had no experience with their oral administration for more than a hypnotic effect. With local anesthesia (including infiltration block and caudal injection) there is a minimum of trauma and of metabolic effects. This is ordinarily an ideal anesthetic where it can be applied with complete satisfaction. Its limitations are chiefly those of time and space in the blocking of all nerves to the area involved

Effect of the Handicap on the Choice of Anesthetic

In actually choosing the best anesthetic for a given handicapped patient, two factors must be kept in mind. First, the advantage of that particular anesthetic in relation to the type and degree of handicap; and second, the disadvantage of that anesthetic in relation to the latter. Consequently it is impossible ordinarily dogmatically to say that one anesthetic or another is preferable for all instances of a given handicap. The factors pro and con must be carefully weighed in each case, though there are certain general principles which apply. Perhaps this situation can be expressed in a formula as follows:

The choice of anesthetic = advantage x handicap—disadvantage x handicap. Let us see now how this is applied to individual types of handicaps.

Diminished cardiac reserve. Nitrous oxide-oxygen is a very simple and satisfactory inhalation anesthetic in the majority of patients. The rapid recovery and minimum metabolic changes as advantages are very satisfactory with this handicap. However, the venous congestion and anoxemia associated with it greatly augment the negative side of the expression. Consequently this anesthetic should not be used in the presence of markedly diminished cardiac reserve. Ether on the other hand has no serious effect upon the heart, in fact it probably has a mild stimulating action. It does not produce venous congestion and is a satisfactory anesthetic for moderate degrees of diminished cardiac reserve. Well compensated valvular lesions are not serious handicaps from the standpoint of the anesthetic. However, if the myocardium is maximally in-

volved, there is no anesthetic that is less harmful than local anesthesia in carrying out a minimum procedure under it.

Diminished kidney function. Here the factor of metabolic effects is important and consequently an anesthetic should be chosen that does not harm this element. Nitrous oxide-oxygen, with a minimum of ether if necessary for relaxation, answers very well where the operation is more extensive than can be done under local anesthesia. The basal anesthetics and full ether anesthesia should not be used in this case.

Hypertension and arteriosclerosis. An anesthetic is not desired that throws an added strain on the arterial system and also under these conditions a sudden drop in blood pressure is probably more serious than in normal individuals. In marked degrees of hypertension, ether is probably superior to nitrous oxide-oxygen as a consequence of the former limiting factor. And in view of the particular danger of a sharp drop in blood pressure, spinal anesthesia and avertin are also contraindicated here. Moderate degrees of hypertension do not constitute a serious handicap. In arteriosclerotic disease of the extremities, local or spinal anesthesia is particularly satisfactory.

Obesity. Extensive local infiltration is undesirable on account of the lack of resistance and consequent greater liability to a low grade wound infection in adipose than in other tissues. Severe grades of obesity constitute major handicaps for surgical procedures. Spinal anesthesia is very satisfactory in such cases even for operations that in normal individuals are too simple for this anesthetic such as inguinal hernia. The possibility of cardiac impairment must also be borne in mind in obesity.

Diabetes. With modern methods of control of this condition it rarely need be a serious handicap at the time of operation. Even in most severe grades, the diabetic condition and acidosis can be brought under control within a few hours. Ether is in general contraindicated. If an inhalation anesthetic is used, nitrous oxide-oxygen and ethylene are preferable. However, it is better to give some ether for relaxation than to be seriously handicapped during the operation by rigidity. Spinal anesthesia is an excellent choice if it is technically satisfactory.

Hyperthyroidism. The use of pre-operative preparation with iodine has greatly simplified the problem of operations for hyperthyroidism. Occasionally, however, we are confronted with a patient who is no longer susceptible to improvement in this way, particularly where iodine has unwisely been used too long by the patient or his physician. In such uncommon instances the patient may be in much worse condition than before iodine was given. The alleviation of mental anxiety is an important element in the handling of such patients. The method of "stealing the gland," given us first by Crile with the dummy nitrous oxide inhalation, is very effectively carried out with these basal anesthetics. With amytal, the patient can be told that he is getting glucose intravenously; while with avertin the procedure is very simple, the anesthetist at the same hour for two mornings preceding the day of operation gives the patient rectal tap water. There is no variation from this program on the date of operation except that the avertin solution is substituted for the tap water. The patient goes to sleep without knowing that he is to be operated upon and is transported to the operating room without awakening him. The addition of nitrous oxide-oxygen after avertin does not cause venous congestion as it frequently does when administered alone.

Intestinal obstruction. In the early stages, spinal anesthesia has great advantages over inhalation agents as the intestinal motility is not interfered with and it is not a constant struggle to keep the abdominal contents from pushing up into the operative wound. In the later stages, if actual gangrene of the bowel has occurred, there may be the danger of rupturing the weakened area by augmenting the peristaltic force. If the peripheral vascular deficiency of the late stage has occurred then the danger of a fall in blood pressure becomes significant. At this stage probably no operation is justifiable that cannot be carried out under local anesthesia, usually an enterostomy, and exploration is postponed until the condition of the patient warrants it.

Toxicity-Cachexia. When far advanced, the same reasoning as employed in the late stages of intestinal obstruction applies to this whole group. The patient's reserves will not withstand an operative procedure that is too extensive to carry out under local anesthesia.

Blood loss, shock, anemia. Obviously no operation should be started before the blood volume available for circulation is sufficient to meet the needs of the latter. Specifically if the blood pressure has progressively dropped below 90 with acute hæmorrhage, operation is contraindicated until the circulatory condition has been improved, unless the bleeding is from a large artery. It is perhaps not so generally realized that the blood pressure may be normal or slightly increased with a long continued or repeated blood loss if the process has occurred slowly. This arises through compensatory vaso-constriction to enable the vital organs to

be served. Such a patient, however, is on the verge of a serious break in the circulation from even a very small decrease in the available circulating blood. Consequently a degree of vasomotor paralysis, which, occurring in an ordinary individual, is without great significance, may be fatal in this case. Specifically, I believe that spinal anesthesia and avertin are contraindicated in all cases where there has been any serious impairment in the circulating blood volume whether this is from acute blood loss, shock, or severe anemia. Local or the inhalation anesthetics are preferable for this handicap.

Pulmonary disease. In active or late tuberculosis, operation should be avoided if possible. Probably the secondary results of the operation itself are much more important in lighting up such processes than is any direct effect of the inhalant upon the lung tissue itself. Minute emboli, arising from thrombosis of the small vessels which invariably accompanies any wound and lodging in the involved lung fields, are important causes of lighting up such latent or pre-existent pulmonary disease. Possibly also other circulatory changes arising from the reaction to the operation or to absorbed products from the operative field are significant also in this regard. There is a general prejudice against the use of ether in such cases. This probably has some basis for it and should be regarded. With pre-existent lung pathology when operation is necessary, local anesthesia should be employed if feasible.

Diminished vital capacity. Post-operative pulmonary complications have a much higher incidence whenever the vital capacity is diminished from any cause. Consequently this should be considered and prophylaxis instituted against this danger particularly in such cases. If the patient does not have tuberculosis he should receive hyperventilation at the end of operation and his position in bed frequently changed to overcome the hypostatic factor. The cardiac function should also be considered. A careful study of a group of patients with epigastric incisions shows that invariably after this procedure the lungs occupy a diminished volume and hypoventilation is present. Work is being carried out at the present time in an effort to overcome continuously this hypoventilation without inducing secondary harmful effects. Probably this factor of preventing hypoventilation is the most important one in connection with the anesthetic problem in these patients with diminished vital capacity.

Conclusions

1. The choice of the anesthetic, usually a matter of personal preference and convenience, becomes important in the handicapped patient.
2. Each anesthetic has certain advantages complicated by its own disadvantages.
3. In each case the choice of the anesthetic is derived from carefully weighing its advantage against its disadvantage for the particular type and degree of the handicap.

HISTORY OF THE MEDICAL SOCIETY OF THE COUNTY OF RENSSELAER

By W. B. D. VAN AUKEN, M.D., TROY, N. Y.

The report of the Historian at the one hundred and twenty-fifth anniversary dinner of the Medical Society of the County of Rensselaer, held in the Hendrik Hudson Hotel, Troy, N. Y., December 10, 1930.

SIXTEEN years before General Grant was born, in the days when doctors of medicine were paid by voluntary donations from their patients, consisting of fruit, vegetables, wood and other necessities of life, a group of twenty physicians comprising all the medical men of Rensselaer County, gathered together July first, 1806, and organized the Medical Society of the County of Rensselaer. This was six months before the date of the actual founding of the New York State Society. Fifteen years before our society was organized there was only one doctor in the entire county. On our thirty-ninth birthday there were twenty-five, on our seventieth, forty-one, on our eighty-fourth, eighty-seven, about one hundred on our hundredth and tonight we find one hundred and twenty physicians in Rensselaer County.

A few of the men who organized our society were called Aaron, Benjamin, Abner, Moses, Ashner, Eli, Hezekiah, Samuel, John and David.

Doctor Reed B. Bontecou at the age of eighty-two was the historian at our centenary dinner given at the Troy Club on February twenty-second, nineteen hundred and six. His report is now a part of permanent records in "Landmarks of Rensselaer County, New York," by George Baker Anderson. This report is too lengthy to abstract and those interested may read it by applying to the Rensselaer County Court library.

Doctor Bontecou, a nationally known surgeon, was called the Napoleon of Surgery. He was among the first in the country to have closed a typhoidal perforation of the bowel. He was assisted at this operation by his student, Doctor H. C. Gordineer, whom we have all known and whose memory we hold dear. In eighteen forty-four, Doctor Bontecou reported witnessing the

ligation of the left subclavian and amputation of the right shoulder while in New York, both of which were done without anæsthesia He was the first man to call the attention of our society to the use of Diphtheria antitoxin He said that membranous croup first appeared in Troy in eighteen fifty-eight and reported several cases cured by antitoxin in eighteen ninety-five Doctor William P Seymore in the same year mentioned eight recoveries out of nine cases of membranous croup which he had treated by intubation, in four of which he used antitoxin Doctor Bontecou was an accomplished naturalist In the early 'fifties he was sent down to the Amazon by the Smithsonian Institution where he collected some flora and fauna.

Doctor John Wright, a preceptor of Doctor Bontecou, was the first man to make ether and chloroform in Troy He used it to anæsthetize a pet raccoon Doctor William P Seymore another of our early members was an occasional sufferer of typhlitis as it was called He told Doctor Bontecou that when he had the next attack, he wanted Bontecou to remove his appendix Records are not available to show whether Doctor Seymore died with or without his appendix Appendectomy was a new operation in those days, Doctor D W Houston being among the first, if not the first, to do an appendectomy in this city

Doctor Leroy McLean, Surgeon-in chief at the Troy Hospital in eighteen seventy-four, performed a series of six Oesophagostomies for the removal of false teeth, the first of its kind in the country, antedating Doctor Cheever of Boston Doctor E D Ferguson with his state-wide popularity as a consultant, his unusual and magnetic personality, as well as his ability as an organizer, was also a great builder, as well as a great insurrectionist of our society His picture is among those in our society room at the Health Center

Members of our Medical Society have been among the founders of all the hospitals of Troy The Troy City Hospital was the first Doctor Matthias Burton was the first doctor to work in that institution It was located on the corner of Fifth Avenue and the New York Central railroad In those days the chief method of transportation was the railroad and canal boats It was not uncommon for Doctor E D Ferguson to flag freight trains or any other train to get out in other parts of the state as a consultant A number of years later some of our members were instrumental in the foundation of the Samaritan and still later, the Leonard Hospitals

Our society has not been without its storms In addition to the loss of forty per cent of our members who were in active Civil War service we were nearly ruined by a break in our ranks which occurred in eighteen eighty four Two years previous (eighteen eighty-two) the New York State Medical Society had declared themselves in favor of consulting with homeopathic physicians This was contrary to the code of the American Medical Association and also contrary to the ethics of Doctor Ferguson and a number of his followers Through his leadership part of our society divided into a New York State Medical Association, not in favor of homeopathic consultations leaving the regular Rensselaer County Society a component of the State Medical Society, under the leadership of Doctors Blatchford, Seymore and Bontecou Fourteen years previous to the split Doctor Hubbell was called on the carpet of our County Society for condescending to consult with one of the irregular homeopaths and that prejudice had not died out

Doctor Ferguson's influence was state wide and as president of the Secessionists he continued his activities through eastern New York, holding meetings at his office and elsewhere

A number of our members were in the habit of attending both society meetings One of them, our present treasurer, Dr O F Kinlock, held office as secretary in both organizations at the same time In nineteen hundred and five, the New York Medical Association dissolved and most of its membership united into one body, our present Medical Society of the County of Rensselaer In spite of the merger in nineteen hundred and five, a contention still existed against homeopaths and it was not till nineteen hundred and eight that this was thrashed out and the first homeopath, Doctor Holmes of Lansingburg, was elected to our membership

Doctor Bontecou's report as historian gave the names of all the presidents with their term of office from eighteen hundred and six to eighteen hundred and ninety-seven, and to complete his work, I have listed here the presidents and their secretaries from eighteen ninety-seven to nineteen thirty one

Presidents	*Secretaries*	*Year*

A. F. Benson	Wm. Van Auken	1929
C. F. Sproat	J. F. Connor	1930

Our society has had eighty-three presidents since its beginning, twenty-eight of whom served two years, three, more than two years and the rest only one year. I believe the finest set of minutes were kept by Doctor J. F. Coughlin, whose term of office as secretary was four years; the longest of any secretary during the past twenty-five years.

Quackery and public advertising have been kept from our midst through the agency of our society. The first one to advertise was the last. In seventeen ninety-three, Doctor John London, the third physician to settle in Troy, ran an advertisement in the *American Spy,* a Lansingburg publication. It ran as follows: "The subscriber, having finished the studies of Physic and Surgery and man-midwifery at the University of Edinburgh and practiced in Europe for some years past, now offers his services to the inhabitants of Troy." In nineteen hundred and nine, a certain Mr. Delfino who illegally posed as a doctor left town as a result of our activities.

As far back as our records are available our regular meetings were held in the afternoon, until eighteen hundred and ninety when the hour was changed to eighty thirty p.m. Our usual meeting place was in the basement of the city hall or the common council chambers. In nineteen hundred and three our regular meeting place changed to the County Court House and in October, nineteen hundred and twenty-five, to the Health Center, corner of Seventh Avenue and State Street.

The last revision or amendments to our constitution and by-laws was made in nineteen hundred and six, at which time the seal of the society was procured. Five hundred copies of an approved diploma for membership were ordered in nineteen hundred and eight.

Our average attendance at regular meetings for the past twenty-five years, with a membership from ninety to one hundred and twenty-five varies between twenty and forty-five.

A notorious fact of history is the continued annual depletion with an occasional deficit treasury. In eighteen hundred and eighty our annual dues were two dollars to the State society and one dollar for our local society. In nineteen hundred and five our local fees were raised from one dollar to two dollars, where they remained till last night when an amendment was duly made to our by-laws requiring three dollars instead of two dollars.

During the past twenty-five years our society has been responsible for the endorsement of the plans for a new Tuberculosis Sanitarium (1908-1910). For an action favoring a large appropriation for the new State Medical Library (1911), for the improvement of Troy's water supply (1891-1911), and hence the almost total obliteration of typhoid fever which was annually taking many lives in Rensselaer County, as well as making invalids of hundreds of people for weeks and months at a time. For the improvement of the city's milk supply (1905-to date), thus greatly reducing the incidence of sore throat, and other infectious diseases as well as the prevalence of Tuberculosis.

Innumerable scientific papers, some of world-wide and lasting importance have been presented by our membership and by merited specialists from other medical centers for instruction and assistance to our members. We still have with us a surgeon, Doctor J. B. Harvie, who was one of the first to do a Gastrectomy, May eleventh, eighteen hundred and ninety-nine. It was the fourth successful case on record; the first being done in Switzerland, the second in Boston and the third in San Francisco. Our society has been blessed by authors of medical text-books, by scientific men who have been in demand by other societies as lecturers and by our nearby college of medicine as instructors and directors of departmental activities.

All these advances have been made in spite of the scarcity of material for humane dissection as well as the indifference and objection of the public to post mortem examinations. Our progress has been very creditable when one considers the antivivisectionists who have been persistent in their efforts and when one thinks of the objections that have been raised to the simple quarantine of communicable disease and the early opposition to Diphtheria protective inoculations.

The years of nineteen hundred and sixteen to nineteen hundred and nineteen were very trying times. Fifty-eight per cent of our ablest members were gone to the World War and the remainder were besieged on the one hand by the demon, compulsory health insurance, which we believed would ruin the very foundation of medicine, and on the other, by the terrible influenza epidemic, which took its horrible toll of lives and taxed us to the utmost. But we have passed by all these obstacles and are now stronger and better men for such experience.

Our society is now ready to enter another one-quarter of a century of activities. May we ever hold fast the lessons learned by our forefathers and advance to a newer and better knowledge of how to prevent and to overcome the greatest of all misfortunes—ill health.

INCIDENCE OF POSTPARTUM HEMORRHAGE*

BY WILLIAM SIDNEY SMITH, M.D., F.A.C.S., BROOKLYN, N. Y.

From the Department of Gynecology and Obstetrics of the Brooklyn Hospital

THE obstetrical division of the gynecological and obstetrical department of the Brooklyn Hospital averages a trifle over nine hundred admissions a year: ward and private patients in nearly equal numbers. There is no ambulance service connected with the hospital, yet each year there are a number of referred obstetrical emergencies. Patients are delivered by the head of the department, his associates and assistants; by internes and clinical assistants under supervision; and a few patients are cared for by the courtesy staff.

With the above paragraph as a short analytical description of the division, let us briefly review the incidence of postpartum hemorrhage in nine thousand consecutive ward and private deliveries, covering a period, from January 1, 1920 to January 21, 1930.

The author is at once confronted with the question, how much blood loss may a patient have at the end of the third stage of labor, in order to properly classify it as a postpartum hemorrhage? In some clinics there is an attempt made to measure the blood lost at the end of labor, and where this technique is followed it may be easy and accurate to say that a blood loss in excess of 500 or 600 cubic centimeters should be considered a hemorrhage.

At the Brooklyn Hospital, we have never attempted to measure nor to estimate this blood loss in figures. Our custom is to note whether the patient has slight, moderate, or excessive bleeding at the end of labor, and to note any clinical manifestations that may be the result of the bleeding. In these nine thousand cases all those who had more than a moderate postpartum blood loss have been classed in the hemorrhage group—even though the hemorrhage was noted as moderate and without clinical evidence of blood loss, nevertheless, the case was recorded in the hemorrhage group in order to have the standard conform as nearly as possible to that of Ahlfeld,[1] Cragin,[2] DeLee,[3] and Williams.[4] To evaluate these case records as fairly as possible, all questionable or borderline cases were submitted to my colleagues, Dr. Eliot Bishop, and Dr. Florence Wilson, before final decision.

It is of interest to give a short history of the evolution of the technique of the third stage of labor which is used at the Brooklyn Hospital. In 1899, Robert L. Dickinson[5] published an illustrated article in the *Brooklyn Medical Journal*, the title of which was "Lifting and Manipulation of the Uterus Through the Abdominal Wall to Control Postpartum Hemorrhage"—The author clearly states that he refers to bleeding from an empty uterus, and his technique was to raise the uterus out of the pelvis by abdominal manipulation while the patient was under anesthesia. One hand grasped the lower uterine segment to pull it upward out of the pelvis and to compress it while the other hand grasped the fundus and compressed that portion of the organ. He makes the point that, unless the uterus is pulled up out of the pelvis, the vessels in the broad ligament are lax and pour out blood, and also that unless the uterus is pulled out of the pelvis it is impossible to grasp enough of the organ to compress it efficiently.

Dickinson's method of manipulation and lifting the uterus did not come into general use at the Brooklyn Hospital until fifteen years later, when it was adopted by the late Ralph H. Pomeroy. He also taught that, in patients who have a tendency to excessive bleeding at the termination of the second stage, the only safe uterus is the empty uterus. For this reason it was his custom, if the patient were under anesthesia, to express the placenta as soon as there was any evidence of separation, which is usually about the time of the first uterine contraction after the birth of the child. Another point on which he laid great stress is, "that the time to stop a postpartum hemorrhage is before it begins." His technique was, after expressing the placenta, to raise the uterus out of the pelvis by exerting pressure backward and upward with his fingers placed just above the pubes. This maneuver brought the uterus out of the pelvis and it was held out of the pelvis for a short time by an assistant who stood at the patient's side. If there were more bleeding than usual, Dr. Pomeroy, himself, took a position at the right side of the patient, and placed his right hand, ulnar border down, across the lower uterine segment, and exerted pressure upward and backward against the spine. The action of his right hand placed the broad ligaments on the stretch, and compressed the lower uterine segment. At the same time, he placed his left hand, ulnar border down, just above the fundus. He thus held the uterus, as one might hold a ball, between his two hands, and could compress it, exert stimulation and prevent the organ from ballooning with blood. As soon as the uterus began to contract properly, an assistant took his place and held the fundus until it remained contracted. Occasionally, it would be necessary to use a lifting vaginal gauze pack to hold the uterus out of the pelvis for several hours. For the last twelve years of Dr. Pomeroy's life, during which period I was actively engaged in assisting him, I never saw him pack a uterus.

W. Stoeckel[6] concludes from a study of nearly a million cases in 1925, that the mortality from

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1930.

postpartum hemorrhage due to atony of the uterus is twice as great in patients in whom the utero-vaginal tamponade is used, as it is when this method is not employed, and H. C. Burgess[7] states that he himself has never packed a uterus.

When George H. Ryder[8] published his paper on the use of pituitrin at the end of the second stage of labor, Pomeroy at once accepted the proposition and used it as routine practice on hospital patients delivered under anesthesia. He thought pituitrin given at the beginning of the third stage of labor hastened and strengthened the first contraction of the uterus, and was an aid to his practice of expressing the placenta at the first uterine contraction.

Our third stage technique is as follows:—Patients are delivered under anesthesia with two doctors gowned and gloved. One cubic centimeter of obstetrical pituitrin is given as soon as the child is born. The operator holds the baby by the feet, the assistant cares for the cord and places the baby in a reception box. About three minutes after the administration of the pituitrin, the operator places his hand on the fundus and waits for the uterus to contract, at which time gentle pressure is exerted on the fundus or at the cornu, and the placenta is usually expressed easily. The uterus is then pushed up out of the pelvis by abdominal manipulation and held there. Occasionally, a placenta is retained for a longer or shorter period. If there is no bleeding we leave it alone, and frequently send the patient to bed. Strict instructions are given to watch for bleeding and if that complication occurs we attempt to empty the uterus by expression, and if that is impossible we extract the placenta manually, for we believe that in order to control hemorrhage the uterus must be empty. If the patient is delivered in emergency without anesthesia or with only one doctor in attendance we do not give pituitrin until the baby has been cared for and the doctor is ready to give his entire attention to the uterus.

Let us now consider the postpartum hemorrhages in these nine thousand consecutive deliveries of ward and private patients covering practically a ten-year period.

There were sixty-seven postpartum hemorrhages in this group which gives an incidence of a trifle more than seven-tenths of one per cent; fifty-two of the hemorrhages were immediate, that is, they occurred before the patient left the delivery table. Fifteen were delayed, which means that the hemorrhage occurred after the patient was returned to bed. There were forty-three mild hemorrhages, and by this term I mean a blood loss which was slight and was controlled by means of pituitrin and lifting the uterus out of the pelvis by abdominal manipulation. In most of these cases there were no clinical symptoms of hemorrhage which required treatment. Nineteen of the hemorrhages were moderate, which means that there was considerable bleeding and enough clinical evidence of hemorrhage to indicate treatment with clysis. Five of the hemorrhages were severe. Three of this group were treated with blood transfusions, either immediately or within forty-eight hours after delivery, and two others received clysis and transfusion.

Clysis and transfusion	2
Vaginal pack	11
Uterine pack	1

In a patient whose uterus has a tendency to remain flabby and when there is a continuous trickle of blood from the vagina after the termination of the third stage, we use a vaginal pack of damp gauze, as much as may be necessary. If we are really concerned about the possibility of a delayed hemorrhage, we apply a tight abdominal binder above. All vaginal packs are removed in not more than twelve hours, and preferably in six.

The one patient in whom an intra-uterine pack was used illustrates some of the fallacies in the treatment of postpartum hemorrhage. A twenty-year-old primipara delivered herself spontaneously of a five-pound baby after a ten-hour labor. One cubic centimeter of pituitrin was given immediately after the birth of the child. The uterus did not contract properly and rather profuse bleeding began. The attending doctor was unable to express the placenta. Bleeding continued and the patient began to show some signs of shock for which the foot of the delivery table was raised and a clysis of 1250 cc. of saline was given beneath the skin. I make the point here, that the placenta should have been removed from this patient before she lost enough blood to show signs of shock. If the placenta could not have been expressed, then it should have been extracted manually, and at once. Twelve hours after delivery, the patient was still bleeding slightly and her condition was rather poor. She was given a

blood transfusion of 500 c c and after half an hour the placenta was manually extracted and in intra uterine pack was inserted However, one hour later there was some bleeding in spite of the intra-uterine pack Five hours later the patient's condition was poor and a second blood transfusion of 1300 c c was given Her condition gradually improved, the intra uterine pack was removed after twenty-four hours, and she was discharged from the hospital in excellent condition twenty days later.

TABLE 4

Deaths

There were two deaths in the 9,000 cases reported in the Brooklyn Hospital (see table 1), a rate of 023 per cent The two cases were as follows

1 Toxaemia of pregnancy in a chronically ill anaemic patient with induction of labor at the

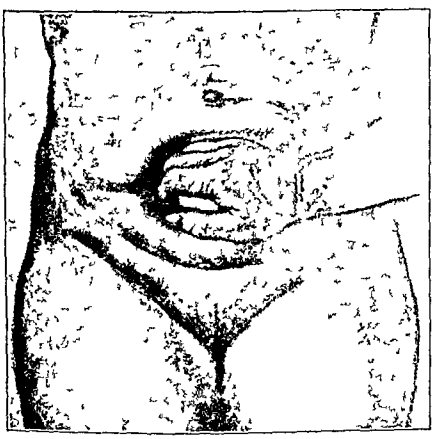

FIGURE 1

The usual seizure of the empty uterus The hand grasps as large an area of the surface as possible by slipping the fingers down the posterior uterine wall somewhat diagonally The flabby abdominal wall permits this

sixth month A very slight blood loss several hours after delivery, probably was enough to upset the circulatory balance and cause death

2 Moderate hemorrhage occurring one hour after delivery in a patient with central placenta previa who had lost considerable blood before the termination of labor

I am not at all sure that the toxaemia case should be classed as a hemorrhage death One of my colleagues believes that it should not be classed in this group I will give a brief history of the case before judgment is passed

A forty year old primipara entered the hospital in 1924 with a diagnosis of neuritis and anaemia of unknown origin After she had been in the hospital for two months and had skipped two periods a pregnancy was discovered She was discharged in poor general physical condition The patient was readmitted at the sixth month of

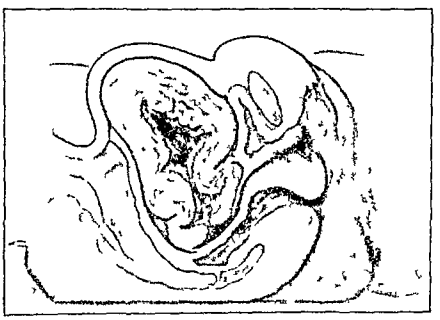

FIGURE 2

The emptied uterus grasped from above and crowded into the pelvic cavity Counterpressure against bony walls is only possible on a limited surface posteriorly or laterally The doubled up or 'squatted' uterus has a gaping cavity Actual uterus from Barbour's frozen section

pregnancy still suffering from anaemia and loss of weight Nephritis and accompanying high blood pressure were added complications A rectal tube was inserted into the uterus to induce labor, which started forty-eight hours later, and in six hours the patient delivered herself spontaneously of a two-pound macerated fetus No pituitrin was given at the end of labor The placenta was allowed to separate spontaneously, and it came away thirty seven minutes after the birth of the child There was very little bleeding at the time and the patient was returned to bed in apparently about the same general condition as before labor Five hours after delivery, the nurse noted that the lochia was rather profuse The patient was given two hypodermatic injections, one of morphine sulphate grs 1/6 and one of ergotole mxx Slight bleeding continued which was no greater in amount than rather profuse lochia, and no particular alarm was felt for the patient After four hours of this slow leak the pulse rate began to increase and the blood pressure began to drop A hypodermoclysis of 1000 c c of saline was given beneath the skin and preparations were made for a blood transfusion, but the patient died before it was given My opinion is that this was a relative postpartum hemorrhage; that is, a very slight blood loss upset the circulatory balance in an anaemic and toxic patient Was this death due to actual blood loss, or was it due to shock and hemorrhage into her own veins?

band of the patient, an obstetrician and gynecologist of note, and also my colleague, Dr. Eliot Bishop, consider this is not a case of postpartum hemorrhage. If we accept their opinion then in this series of nine thousand cases we have had but one death, an incidence of .012 per cent.

The second death occurred in 1922. The patient was a thirty-six year old Italian who had nine previous pregnancies. She was at term and gave a history of considerable bleeding two days, and again a few hours before admission to the hospital. There was no bleeding when the patient was admitted, and she was in fair condition with a normal blood pressure, a slightly elevated pulse and an audible fetal heart. A diagnosis of central placenta previa was made by vaginal examination which caused profuse bleeding. The vagina was at once packed full of damp gauze and the patient anesthetized. The operator succeeded in doing a Braxton-Hicks version without great difficulty, introducing two fingers through the cervix and placenta and grasping a foot. A considerable gush of blood was controlled by gentle traction on the child's leg. This traction was continued, labor pains began, and the child was delivered more or less spontaneously two hours after the version. The placenta came away at once and was followed by considerable hermorrhage. The vagina was packed full of damp gauze, but no abdominal binder was applied. This procedure controlled the bleeding and though the patients pulse was rapid her general condition was not alarming. One half hour later, as there was no vaginal bleeding, the patient was returned to bed. Shortly thereafter blood began to show through the vaginal lifting packs. Fresh vaginal packs were inserted, but the patient died in a few moments, a victim of repeated hemorrhages.

TABLE 4
COMPARATIVE TABLE
POSTPARTUM HEMORRHAGES

	Deliveries	Incidence		Mortality
Sloane Hospital	2,000	10.5%		Not reported
Johns Hopkins Hospital	1,000	13% 1%	Lost 600 cc. Lost 1500 cc.	About .05%
Chicago Lying-in	45,000	2%	Severe Hem.	.007%
W. Stoeckel Berlin	971,487	8%	Lost 1500 cc.	.28%
Berwind Maternity	4,200	2.4%		Not reported
Jewish Hospital Brooklyn, N. Y.	2,293	1.5%		.04%
Manhattan Maternity	13,000	1.7%		.03%
Bellevue Hospital 2d Div.	4,396	1.5%		.11%
Woman's Hospital	1,041	1.3%		.2%
Brooklyn Hospital	9,000	.74%		.023%
Montreal Maternity	18,720	.32%		.01%

A review of the literature gives some interesting statistics for comparison. Cragin[2] cites a series of 20,000 deliveries at the Sloane Hospital, prior to 1916, in which there were 2118 patients who had a postpartum blood loss of sixteen ounces or over, which gives an incidence of 10.5 per cent. He does not mention any deaths.

Williams[4] observes 600 c.c. postpartum blood loss in 13 per cent of 1,000 consecutive deliveries and notes 1500 c.c. or more blood loss once in 100 deliveries, or 1 per cent. He states that with proper treatment a fatal case should not occur more often, on an average, than once in 2,000 or 2,500 deliveries. DeLee[3] states that in 45,000 consecutive deliveries at Chicago Lying-in Hospital Dispensary there were only three deaths from postpartum hemorrhage, but that there were twenty more patients who came very near death. He feels that severe postpartum hemorrhage occurs in about 2 per cent of deliveries, and that in experienced hands a death is rare. Rice,[9] at the Manhattan Maternity in 1916, notes an incidence of 222 postpartum hemorrhages in 13,000 consecutive deliveries, or 1.7 per cent, and that there were four deaths in his series, or .03 per cent. Hornstein,[10] at the Berwind Maternity in 1922, finds 100 postpartum hemorrhages in 4,200 consecutive deliveries, an incidence of 2.4 per cent. The deaths in his series were not noted. In 1925, W. Stoeckel,[6] formerly of Leipzig and now director of the gynecological department of the University of Berlin, in a very elaborate monograph, "Pathology and Therapy of Postpartum Hemorrhage," reviews not only the literature regarding postpartum hemorrhage, but also analyzes 971,487 labor cases about which he gained information through questionnaires. The monograph is divided into two parts, that which concerns the normal, and that which relates to the pathological third stage of labor. He believes the upper limit of blood loss in a normal case is 500 c.c. Among the 971,487 labors, 582 women died of hemorrhage, but only .28 per cent died of hemorrhage due to pure "atony" of the uterus. The others died of rupture of the uterus, placenta previa, etc. Of the total number who had excessive bleeding, 7,918 lost more than 1500 c.c., and of this number 3.5 per cent died. He goes on to say that, in the prophylaxis of atonic bleeding, massage is the best uterine stimulant; manual removal of the placenta should be done earlier and more frequently than it has been done; and that the mortality from "atony" of those who employ utero-vaginal tamponade is twice as great as the mortality of those who are opposed to this procedure. Burgess[7] cites 18,720 deliveries at the Montreal Maternity covering a period from 1906 to 1924. In this series there were sixty postpartum hemorrhages, or .32 per cent with two deaths, or .01 per cent. Ronsheim[11] reviews 2,293 deliveries at the Jewish Hospital in Brooklyn, N. Y. during 1928. He notes thirty-one cases of postpartum hemorrhage, five of which were of

a serious nature, and that death occurred in one patient. His incidence of hemorrhage is a trifle less than 1.5 per cent, and his mortality is .04 per cent. The late Harold Bailey[12] reviewed 4,396 deliveries from the second division of the Bellevue Hospital Maternity service in 1928, and he reports 66 hemorrhages, or an incidence of 1.5 per cent. There were five deaths, or .11 per cent. A personal communication from Woman's Hospital, New York City, reports a series of 1041 deliveries during the last two years. Fourteen of this series or 1.3 per cent had a postpartum hemorrhage. Two patients died which gives a mortality of .2 per cent. One of these patients had a second degree hemorrhage and died on the eighth day from acute nephritis, and the other had a first degree hemorrhage but died the same day from shock and hemorrhage.

SUMMARY

1. The incidence of postpartum hemorrhage in a number of large obstetrical departments varies between 13 per cent and .32 per cent while the mortality varies between .28 per cent and .007 per cent. The average incidence is 3 5 per cent and the average mortality is .09 per cent.

2. By the Dickinson-Pomeroy method of third stage technique the incidence of postpartum hemorrhage at the Brooklyn Hospital is .74 per cent and the mortality is .023 per cent.

3. We believe that in the control of postpartum hemorrhage the intra-uterine pack is not necessary, and that the lifting vaginal pack, with or without an abdominal binder, may occasionally be required.

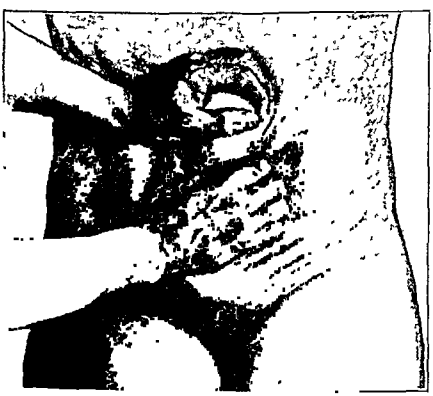

FIGURE 3

The entire uterus is lifted out of the pelvis by seizing it through the abdominal wall, and compressed against the spinal column. The lower hand grasps and manipulates the cervix. Lifting is only feasible where the round ligaments contract poorly.

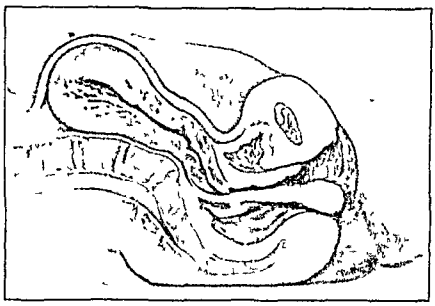

FIGURE 4

Section showing uterus immediately after expulsion of placenta raised out of pelvis to make cervix accessible for seizure and press fundus against spinal column. Pressure is exerted all over uterine walls, cavity is collapsed, uterine arteries are under tension.

4. The dicta that "The only safe uterus is an empty uterus" and that "The time to stop a postpartum hemorrhage is before it begins" should be remembered.

5. The Dickinson-Pomeroy method of third stage technique consists of: (a) The administration of pituitrin as soon as the child is delivered, provided the patient is under anesthesia and an assistant, as well as the operator, is present. (b) The prompt expression of the placenta at the time of the first uterine contraction after delivery of the child. (c) The immediate lifting of the empty uterus high out of the pelvis by abdominal manipulation, with a grasp which lifts and compresses the lower uterine segment against the spinal column with one hand and compresses the fundus, with or without massage, with the other hand. (d) The occasional use of a second dose of pituitrin and the administration of ergot. (e) The occasional use of the lifting vaginal pack, with or without an abdominal binder.

6. The incidence of and mortality from postpartum hemorrhage in this large series of cases at the Brooklyn Hospital, is so low that the Dickinson-Pomeroy method of third stage technique should be considered standard.

CONCLUSIONS

1. Unceasing vigilance in the control of small blood losses at their start, is the method by which the obstetrician may lessen the incidence of postpartum hemorrhage.

2. It is evident that the intra-uterine pack is not necessary in the prevention, or treatment of postpartum hemorrhage.

3. The incidence of, and the mortality from

postpartum hemorrhage in this large series of cases is so low that the Dickinson-Pomeroy method of third stage technique should be considered standard.

DISCUSSION BY GEORGE HOPE RYDER, M.D., NEW YORK, N. Y.

This paper of Dr. Smith's has interested me greatly. Prevention of hemorrhage in the third stage of labor is one of the most important things in obstetric care. Too much praise cannot be given those in the Brooklyn Hospital for adopting and using the Dickinson-Pomeroy method of holding the fundus after the birth of the child. This method, as described by Dr. Smith, with the meticulous care in the prevention of hemorrhage, and the personal attention of the operator himself, gives one a thrill of joy in the hearing. The excellent results obtained, only 67 cases of postpartum hemorrhage in 9,000 deliveries, an incidence of .74 per cent, is above criticism. This method, I am convinced, if universally adopted, would do much to lessen the terrors and evil consequences of postpartum hemorrhage, throughout the country. It is really appalling to see the careless indifference of many obstetricians to hemorrhage, in the third stage of labor. The operator so often gives his attention to the baby, or to other matters, and allows a hemorrhage to flow steadily on, till suddenly symptoms of beginning shock and collapse in his patient, awaken him, with a start, to frantic efforts to stop a hemorrhage which never should have begun. Such hemorrhages, even when not immediately dangerous, often have bad after effects, lessening resistance to infection, diminishing the chances of successful nursing, and preventing a prompt return to health and happiness. And, unfortunately, as we know, the immediate effects are sometimes fatal.

Too much praise cannot be given to the authors and teachers of this method, and most gratifying it is to hear it described.

The estimated hemorrhage is not scientifically accurate. However, I believe it is surprisingly so practically. At the old Sloane Hospital, under Dr. Cragin, it was the custom to weigh all hemorrhage, which could be caught in a basin, and to estimate the amount lost besides. The two added together, was the total hemorrhage. Frequently I have asked the nurses and doctors present at a delivery, to guess the amount caught in the basin, before measuring it; and the estimate of those constantly in the delivery room, I have found remarkably accurate. I believe the estimate of blood loss, as described by Dr. Smith, with the careful observance of symptoms in the mother, is probably quite accurate. His statistics are therefore very remarkable, especially as the deliveries were conducted by many different doctors, including, associates, assistants and internes. Most heartily do I agree with his two slogans, "the time to stop a postpartum hemorrhage is before it begins," and "an empty uterus is the only safe one."

However, admirable as I believe the Dickinson-Pomeroy method to be, I do not believe the method as outlined is sufficient. Holding the fundus skillfully, eternal vigilance in the third stage, the administration of pituitrin at the beginning of the third stage, the vaginal pack behind the cervix for some, these we have seen give excellent results. But they are not enough.

I believe intra-uterine tamponade is the sheet anchor, on which we must rely at times, to keep us off the rocks of disaster. This with the routine administration of some good preparation of ergot postpartum, often in repeated doses, will alone give us complete protection in bad cases. Dr. Smith's paper does not mention the use of ergot postpartum as a routine.

At the old Sloane Hospital our slogan was, "when in doubt, pack and pack early." Dr. Smith has mentioned Dr. Cragin's statistics for postpartum hemorrhage in the first 20,000 deliveries at the Sloane Hospital. It was my good fortune to help Dr. Cragin prepare all the statistics for these 20,000 deliveries. As Dr. Smith has said, there were 2,218 postpartum hemorrhages in these 20,000 deliveries, an incidence of 10.5 per cent. He says the mortality is not mentioned. This I find is listed as 2, 2 in 20,000, or 1/100 per cent for the whole number of deliveries, or 2 in 2,218 cases of postpartum hemorrrages, 9/100 per cent.

These postpartum hemorrhages are listed as follows:

1st Degree Hemorrhage (16 to 24 oz.) 1,286 —6.4 per cent.

2nd Degree Hemorrhage (24 to 32 oz.) 528 —2.6 per cent.

3rd Degree Hemorrhage (32 oz. or over) 304 —1.5 per cent.

Deaths 2 (as mentioned), one in a woman with a torn cervix, following Caesarian Section, not packed.

Deaths from hemorrhage from all causes in 20,000 deliveries, are listed as follows:

Placenta previa, 13.
Accidental hemorrhage, 4.
Ruptured uterus, 14.
Ruptured ectopic, 2.
Postpartum Hemorrhage, 2.
Total all hemorrhages 35.

It was the custom to pack with intra-uterine tamponade all cases under suspicion of hemorrhage. All severe placenta previas, accidental hemorrhages, bad toxaemias, flabby or unduly distended uteri, or uteri tired from prolonged labor —all were packed at once. It was believed that early prompt packing in doubtful cases was the best prophylaxis against postpartum hemorrhage

Because of Dr. Smith's paper, I looked up my own private records in reference to postpartum hemorrhage. I find that in 1,200 consecutive deliveries of private patients, I have 9 postpartum hemorrhages listed. By postpartum hemorrhage is meant the loss of 16 ounces or more of blood, the same estimate as was used in the early Sloane records and at the Brooklyn Hospital. Nine postpartum hemorrhages in 1,200 deliveries, or an incidence of .75 per cent, almost exactly the same incidence as in the series of Dr. Smith's which was .74 per cent.

Of these 9 postpartum hemorrhages; 8 had uterine tamponade.

There were no delayed hemorrhages.

No transfusions were necessary.

There were no deaths.

7 had no temperature, at any time, of 100 6/10 or over.

2 had temperatures of 100 6/10, but for one day only.

All were given preparations of ergot postpartum.

Looking further into these statistics, in this connection, I find that in the 1,200 deliveries, intra-uterine tamponade has been performed 12 times, or in 9 3/10 per cent of the cases;

23 were after normal labor.

76 followed operative delivery per vaginam.

13 were done as a routine measure in Caesarian Section.

51 followed labors of 12 or more hours duration.

61 followed labors of less than 12 hours duration. This includes the 13 Caesarians.

8 of the 112 packed had hemorrhages severe enough to be listed as postpartum hemorrhage, i e, 16 oz. or more.

104 had blood loss estimated as less than 16 oz.

83 had no temperature during the puerperium, of 100 6/10 or over.

29 had temperatures of 100 6/10.

Of these 29,

20 had temperature lasting 1 day only.

9 had temperatures lasting more than one day, listed as follows;

4 due to pyelitis

2 due to grippe

3 due to mild uterine infection, not influencing the course of the convalescence.

It seems safe to say that in no case did the tamponade of the uterus do any harm. There were no deaths from shock or hemorrhage No delayed hemorrhage. No transfusions were necessary, and there were no infections of moment. In the 112 tamponades, there were only 8 severe hemorrhages, as stated. The other cases were packed as a prophylactic measure. In some, brisk hemorrhage was starting but was quickly stopped. In others, there was no hemorrhage, but because of atony of the uterus, prolonged labor, undue distention in twin pregnancies, or because of placenta previa or accidental hemorrhage, the tamponade was done to prevent bleeding.

My method of conducting the third stage of labor is much like that outlined by Dr. Smith. Four minims of pituitrin is administered at the beginning. The placenta is expressed or extracted manually at once, in the presence of severe or persistent bleeding. Pituitrin cc. ½ and ernutin cc. ½ by hypodermic injection are given together immediately after the uterus is empty. The ernutin is repeated at intervals of two hours, for three doses in primiparae and for four in cases of multiparae. In case of doubt, the uterus is packed at once with 5 per cent iodoform gauze. The containing jar holds 8 yards of this gauze, 12 inches wide and folded to 1 inch. The packing is done after manually exploring the cavity of the uterus and removing clots or retained membranes, usually under gas and oxygen anaesthesia. One hand with the gauze is passed into the vagina and the uterine cavity is packed with two fingers, against the other hand on the fundus. The gauze jar is held by an assistant. The packing can be done quickly and without shock by this method, and practically without instruments. The sooner it is done, if done at all, the safer.

Doubtless many of these 112 cases packed would have bled very little if not packed. Others, I think, undoubtedly were spared severe postpartum hemorrhages. However, after packing many uteri postpartum, I can truthfully say I have never regretted having packed one, and I have never seen any harm done by intra-uterine packing when this method is used

The gauze is usually removed in 48 hours.

Considering these two sets of statistics, those of the old Sloane Hospital, and mine in private practice, where in each, the policy was to use intra-uterine tamponade at once, in case of doubt; we see that in the first there were 2,118 cases of postpartum hemorrhage in 20,000 deliveries, an incidence of 10.5 per cent, with a mortality of only 2, or 1/100 per cent. In the other there were 9 postpartum hemorrhages in 1,200 deliveries, an incidence of 75/100 per cent, with a mortality of nil.

In Dr. Smith's statistics at the Brooklyn Hospital there were 67 postpartum hemorrhages in 9,000 deliveries, an incidence of 74/100 per cent, with a mortality of 2, or .23 per cent (2.3/100%). The great care shown in the third stage, has brought the occurrence of postpartum hemorrhage down far below that in the old Sloane Hospital (10.5%), and about even with that of mine in private practice; but the mortality, 2 in 67, or 2 8/10 per cent is higher than that of either of the others, 2 in 2,118, or 9/100 per cent in one case and nil in the other.

Allow me to take up for consideration Dr. Smith's three conclusions. His first reads, "Unceasing vigilance in the control of small blood losses at their start, is the method by which the obstetrician may lessen the incidence of postpartum hemorrhage."

This conclusion I cannot indorse too heartily. I believe it most sincerely.

His second conclusion reads, "It is evident that the intra-uterine pack is not necessary in the prevention or treatment of postpartum hemorrhage."

From this conclusion I must dissent just as heartily as I agreed to his first. I think his statistics in no way tend to prove this, but on the contrary tend to disprove it. In other words they tend to prove what I believe, that intra-uterine packing *is* necessary in the treatment of postpartum hemorrhage, and at times is the only measure which will save life.

In Dr. Smith's series of 67 postpartum hemorrhages, only one had intra-uterine tamponade, but two died, both without intra-uterine tamponade. The intra-uterine pack used, I am inclined to believe, may have saved a life, and the same measure promptly used might have saved the lives of the two who died. In other words, if the intra-uterine pack had not been used at all in this series, there well might have been 3 deaths. And if it had been judiciously used three times, there might not have been any deaths at all, in the series.

Considering the one woman who *was* treated by intra-uterine tamponade, we can not feel sure that she would have died without it, but certainly, if she was carefully packed, it was an important factor in her recovery.

Let us examine the two cases that died.

One was a toxic woman in not too good condition. This woman was delivered beautifully One can only admire the method of delivery. She was safely delivered. So far, so good. But what then? After watching her and carefully holding the fundus for a while, she was sent to the ward. There she continued to leak blood slowly and constantly, till finally she died. I believe that if this woman, after her careful and skillful delivery, had been promptly packed at once, then given a hypodermic injection of some ergot preparation, repeated if necessary (watching the blood pressure before doing so)—I believe, in all probability she might not have died. Certainly this constant blood leakage, in an anaemic, toxic, weakened woman, was very dangerous.

The second case was that of a placenta previa. Here again, the delivery was all that could be desired, skillful, careful and according to the best obstetric principles. Again, so far, so good. The woman was delivered in good condition. But what then? After half an hour, she was sent to the ward, where she died of repeated hemorrhages. I can see no reason to believe otherwise than if this woman had been promptly packed, and given repeated doses of ergot hypodermatically, her life might have been saved.

In Sir Walter Scott's beautiful poem, "The Lady of the Lake," there are these lines:

"Ill fared it then with Rhoderick Dhu
That on the ground his targe he threw,
Whose brazen studs and tough bull hide
Had death so often dashed aside."

The Scottish chieftain Rhoderick Dhu, in his duel with James Fitz James, threw away his shield and lost his life. The obstetrician who throws away his intra-uterine packing may lose the life of his patient.

Dr. Smith's third conclusion is, "The incidence of, and the mortality from postpartum hemorrhage in this large series of cases is so low that the Dickinson-Pomeroy method of third stage technique should be considered standard."

To this I cannot agree. The incidence is low, wonderfully low. 67 in 9,000 deliveries. But 2 out of these 67 died, 2 8/10 mortality. With intra-uterine packing, this mortality might have been nil. The Cragin series, with its treatment by intra-uterine tamponade, gives a much higher incidence, 2118 in 20,000 deliveries, but a much lower mortality, 9/100 per cent. The Dickinson-Pomeroy method, supplemented by ergot and intra-uterine tamponade in case of need. This is another matter. This might well be standard. One might well call it familiarly in abbreviation, the "D.P.C. Method," standing for the Dickinson-Pomeroy-Cragin Method.

In closing, again let me express my admiration for, and my approval of the Dickinson-Pomeroy method, which its teaching of care and control in the oft-neglected third stage of labor. But allow me to plead for the use of ergot postpartum and the intra-uterine tamponade, in case of need.

DISCUSSION BY ELIOT BISHOP, M.D., BROOKLYN, N. Y.

As the reader of this paper has stated, I went over these records with him at some length, and I must take issue with him in his reaction. Statistics, most of us feel, are unreliable: they can be distorted to suit one's purpose. In this particular instance I think that Dr. Smith has leaned over backwards in both his incidence of hemorrhage, and in at least one fatal case. He came to his conclusion as to the 67 cases after having read that other reporters had used 500 cc. of blood loss as the amount above which hemorrhage is considered.

A few days after this paper was written an interne made a careful observation on a patient who, he felt, had bled much more than usual, so much so he became concerned. The blood loss was measured, and found on a generous estimate to be 400 cc., which would not list this patient in the hemorrhage group. As we have not been measuring the amounts of blood loss, it is quite likely that many of these 63 patients had less than 500 cc. of blood. On the contrary, many patients listed as having bled excessively did not show anything in the way of symptomatic effect —no pulse elevation, pallor or air hunger. In fact, the latter symptom occurred in but very few instances. I feel very strongly that only 43 cases of Dr. Smith's series should be listed in the hemorrhage group, which would reduce his percentage of incidence to .48 per cent.

In discussing the subject of mortality, I feel that the first case which, as he stated, was the wife of a well-known specialist in our line, ought not to be classed as a hemorrhage. Her husband takes the same stand. This patient had no more bleeding than the average person after she was returned to bed. She was a patient who was vitally sick, though not moribund, and the shock of labor and the ordinary blood loss of the average patient would be sufficient to make her lose her circulatory balance.

I think as a representative of the Brooklyn Hospital that we would be perfectly justified in striking out that first case, which would cut the death rate in half, or to .012 per cent.

As to the second case, many reporters of postpartum hemorrhage have considered only those that bled from atony of the uterus, and the cases of placenta previa are considered entirely separately. If the Brooklyn Hospital statistics were compared with these others it would also have to be omitted. However, to both Dr. Smith and myself this was a postpartum hemorrhage.

Let us again discuss this last case from the point of view of the intra-uterine pack, the use of which neither Dr. Smith nor I can counsel. In the case of placenta previa with bleeding, the source of which must be, in the major part, from the uterine arteries, we feel that a vaginal pack is essential because of its effect on kinking these arteries. Now then! If there has been a laceration, or only a predisposition to laceration of the cervix or lower uterine segment, it would seem to me that a pack against such tissue would extend the laceration. To carry the picture further, if we pack the fundus of the uterus we are packing an area entirely unnecessary, an area away beyond the source of blood loss. This patient was cared for by a clinical assistant, of no great experience. How well he did the version, in what condition he left the cervix, no one can tell. Our method of supervising him and his work we consider as a necessary part of the educational duty of the hospital.

While these remarks may seem in the nature of a rebuttal, they cannot well be put forward by Dr. Smith, because they do not adjust themselves to his premises. We greatly appreciate Dr. Ryder's courteous and painstaking review of the subject. What we cannot accept is his advocacy of an intra-uterine pack. If you will allow my correction of Dr. Smith's figures we feel that the record we have obtained in these 9,000 labors will hold with any series.

DR. WILLIAM SIDNEY SMITH (Concluding)

We use some preparation of ergot postpartum in a majority of the patients. It is not routine, however.

I wish to thank Dr. Ryder for the manner in which he brought out his argument for the uterine pack. I cannot agree with him, however. In packing a uterus the operator packs a hollow viscus, the cavity of which does not remain constant in size. It is impossible to say that the uterus will not fill up with blood behind the pack. Even in the hands of a skillful operator and in the best of aseptic surroundings it is difficult to pack a uterus. The dangers are fourfold, namely: (1) difficulty in executing the maneuver, (2) possibility of perforating the uterus with the packing forceps, (3) infection, and (4) shock to the patient. Surely, we must listen to such an observer as W. Stoeckel when he concludes from the study of nearly a million cases that the mortality from postpartum hemorrhage due to atony of the uterus is twice as great in patients in whom the utero-vaginal tamponade is used, as it is when this method is not employed. I think the exceptionally low incidence and mortality from hemorrhage in these 9,000 cases who were treated without the use of the intra-uterine pack is good evidence that the Dickinson-Pomeroy technique is competent, and that the pack is not necessary.

POST PARTUM HEMORRHAGE

Every medical student is taught the method of controlling post partum hemorrhage by compressing the emptied uterus *downward* into the pelvis. On page 141 of this Journal Dr. W. S. Smith is reporting nine thousand consecutive cases of delivery in the Brooklyn Hospital, Brooklyn, N. Y. by the method of lifting the uterus from below and compressing it against the promontory of the sacrum. An examination of the drawings will show why the method of *lifting* the uterus up to the brim of the pelvis is much more effective than forcing it *downward* into the cavity of the pelvis where there are no resisting parts.

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—No. 15

Public opinion has been directed to medical care in many ways during the last three years. The subject has been studied enough to permit a better conception of its status than was possible even six months ago.

Many half truth statements have been made and a considerable degree of hysteria shown in thoughtless consideration. A striking thing has been the ability of laymen to clothe the half truths in such interesting language that they have a public appeal. Current literature has been quick to publish these interesting stories. Much of the discussion of medical care has been unscientific. Nevertheless, it has served a purpose in directing thought to the subject, and out of it all is beginning to come a degree of unexpected orientation.

In an effort to discharge the obligations of the office of President, I have made this year a comprehensive study of medical activities. medical care, the costs and availability of medical facilities in or for every county in New York State, including the functioning of the Public Welfare Law in each county of the State. The fees of physicians, in general, are not a major factor in the costs of medical care. When the studies of the National Committee started, it was quite apparent, in public opinion outside of medical opinion, that the studies were expected to show that the fees of physicians are a major factor. My own studies thus far show that the fees of physicians, in general, in New York State are not a major factor. In fact, I have found so many cases where the doctor does the work with little expectation of pay that the thought occurs to me that if the true situation were known, it would arouse more public admiration for the profession than now exists.

The Public Welfare Law in every county in which its machinery has been set in motion is taking care of the sickness of those who cannot pay for adequate medical care as well as is now done for those who can pay. Some of the counties of the state are administering this law about as perfectly as human effort ever functions. This is true of all of the counties in which the principle of conference has been used between the medical profession, the hospital superintendents, and the Public Welfare Commissioners. This result has largely been brought about by the Public Relations Committee of the Medical Society of the State and the Public Relations Committees of the County Medical Societies. Of course, there are counties in the state that have not yet established correct administrative organization of this new Law.

Matters of administration considered in a friendly conference between the local hospital, the local profession, and the Public Welfare Commissioner under the direction of the County Medical Society, have regularly resulted in a common understanding that has worked out to the satisfaction of the Public Welfare Commissioner, the hospital, and the local profession; and the indigent patient has received as good treatment as any other person paying under similar expenditure.

The problems of medical care, at least for the State of New York, will work out as the result of conferences now being carried on by organized medicine, stimulating into action the cooperation of the profession of medicine, the hospitals, and the Public Welfare Commissioners.

Nearly all of the counties in New York State have within their boundaries a well equipped hospital. Only three are without hospitals. Many of them are the equal of any other hospital when measured by the results of treatment. I have not been able to find a single case denied admission. Under the Public Welfare Law no case need ever be excluded because of lack of ability to pay. I have visited the hospitals in several of these counties; to mention only a few,—Tioga, Chenango, Wyoming, Jefferson, St. Lawrence, Ontario, Yates, Clinton, Otsego, Suffolk, and Nassau. There is no problem of medical care in these counties.

Strange as it seems, the unscientific and the many half truths appearing in current literature have started enough study to show that the situation regarding medical care is due more to extravagant demands for luxury in sickness than to the costs of competent service, if confined to actual needs. The profession of medicine, if to be blamed at all, is only to be blamed for acceding to the demands of many people in sickness for unnecessary specialism, more than necessary use of laboratory facilities and instruments of precision, and unnecessary expenditure for nursing and insistence upon luxuries, such as, flowers and taxis for friends to come to see them,—two things at least that, perhaps, in health they never ever thought of.

There is a border line class between those who can pay for medical care when divested of its scientific and service luxuries, and those who come under the Public Welfare Law. This is the class whose income does not lift it far enough above the line of providing the necessities of life and who can pay very little for sickness and not at all for a major sickness. For this class, the border line class between the well-to-do and those provided for by the Public Welfare Law, something must be provided.

Perhaps, an expansion of the Public Welfare Law will in time take up this border line class and by proper public education create a public demand that will care for all of this class of self-respecting people who earn too little to provide adequately for sickness outside of the necessities of life. In that case, some form of insurance would be needed; and this would have the approval of the medical profession—the most essential factor in the whole question of health and sickness service.

WILLIAM H. ROSS, M.D.

LEGISLATION

The members of county medical societies are in earnest in their attempts to devise means of giving all practical forms of medical service to all classes of people. Physicians have always been willing to relieve human ills of both body and mind, but they require the assistance of others. In the olden days the burden of assisting the doctor fell upon charitable neighbors; but now the people recognize their civic duty to provide medical and allied services through the municipalities, the State, the counties, the towns, or the cities. The Welfare Law which went into effect only a few months ago promises to solve the more evident problems of the relation of physicians to those financially unable to provide medical services for themselves and their dependents.

The Legislature of New York State will doubtless be asked to consider new plans for more extended and definite applications of the principles of the Welfare Law. When the bills are introduced in the Legislature the time available for their consideration will be brief, —less than three months at most. Every change and amendment of a bill will require time, and the observance of rules which delay action and possibly may give an appearance of opposition when only constructive importance is intended.

It is the duty of physicians throughout the State to read the bulletins of the Committee on Legislation and the Legislative reports in this Journal, and so be ready to give intelligent support to the actions which are decided upon by the members of the Committee.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Dr. George R. Fowler—This Journal of February, 1906, contained the following appreciation of Dr. George R. Fowler of Brooklyn, who died on February 6, 1906, aged 58:—

"Dr. Fowler was a man of indomitable energy. His capacity for work seemed almost without limit. Notwithstanding the vast amount of hospital and private work which he did, he found time to give a large measure of his energy and thought to the general interests of the medical profession. He was always active in the affairs of his medical societies, and was always found taking a firm stand for what he believed to make for the best interests of his profession. He was one of the active movers in the amalgamation of the two great societies of the State of New York. One of the last things to receive his attention was a movement to make accessible to all the members of the State Society the books of the library of the Medical Society of the County of Kings. He had hoped to see consummated a plan to give members of the State Society the privilege of having sent them, upon request, volumes from this large library. With these objects for the general good in his mind, he went to Albany to attend the centennial meeting and reunion of the State Societies. He was stricken with appendicitis on his way to the capital city —the very disease from which he had rescued thousands—and after an illness of ten days, in which every resource of science was exhausted. he gave up his life on February 6, 1906. A system which had been overtaxed by years of unremitting work, failed at the critical hour; and this splendid and much beloved man died because of the great labor he had done for others."

MEDICAL PROGRESS

The Principles of and Some Results in the Radium Treatment of Buccal Carcinoma.—G. E. Birkett, writing in the *Canadian Medical Association Journal*, December, 1930, xxiii, 6, states that radium has improved out of all recognition the outlook in buccal carcinoma, and at the same time it has enriched our knowledge of the disease. Radium treatment has conclusively proved that metastasis to the lymphatic glands is by embolism. It has also shown that there exist quite marked variations in buccal carcinomas with corresponding variation in sensitivity. Almost every carcinoma of the base of the tongue will be of an embryonic, undifferentiated and radiosensitive type; consequently there is a good chance of local cure in almost every case. Epitheliomas of the cheek, lip, floor of the mouth, and anterior third of the tongue are almost invariably of a highly differentiated type, and hence less markedly radiosensitive than those of the preceding type. Practically every case is superimposed on a chronic glossitis of syphilitic origin. In such cases diathermy may have to be used if radium is unsuccessful. In the middle third of the tongue both histological types are found. Prolonged irradiation with gamma rays of low intensity yields the best results. Needles of active length, say 30 cm., are infinitely easier to insert than six separate seeds and they are superior to the seeds. Overtreatment rather than undertreatment should always be the aim, since second applications do not meet as active response as the first. The treatment of the lymphatic area may be summarized as follows: (1) If no glands are palpable, observation at monthly intervals. (2) If glands are palpable and removable, block dissection either combined with implantation of radium or followed by external distance irradiation: (3) If the glands are fixed, implantation of a large number of needles, 30 or 40, after thorough exposure of the neck. By employing methods based on those of Regaud, the author obtained apparent cures for the primary site in buccal carcinoma for 1926, 1927, and 1928 in 38.7, 47.3, and 60 per cent of the cases and where the primary and secondary sites were considered in 27.5, 36, and 45 per cent. In other words the results improved with experience. This emphasizes the importance of concentrating radium treatment at large centers. Radium treatment is a conservative method, in which, if successful, function is restored almost to normal. It possesses many advantages over surgery.

Symptoms and Pathogenesis of the Hemorrhagic Diathesis.—H. Letheby Tidy, writing in the *British Medical Journal*, December 27 1930, ii, 3651, takes the position that the essential cause of the bleeding in the hemorrhagic diathesis is an increase in the permeability of the capillary endothelium. The platelets attempt to protect the weak spots, and are thus removed from the circulation. Increased demands for platelets fall on the bone marrow, which may or may not respond successfully. The normal action of the spleen in destroying defective constituents of the blood increases, and the spleen tends to enlarge spodogenously. This explanation does not tell why the capillary permeability varies and whether there is a primary action of the spleen causing this permeability. In the past the hemorrhagic diathesis has been classified into the following groups: purpura simplex, purpura rheumatica or Schönlein's purpura, Henoch's purpura, and purpura hemorrhagica. The more correct view has been gaining ground that these groups possess common factors, and to some extent represent degrees of severity. As a complete entity the hemorrhagic diathesis falls into three groups: (1) Pure primary hemorrhagia of all grades, the symptoms attributable to anemia being the most prominent. (2) Pure primary urticaria of which the characteristic symptoms are abdominal colic and joint pains. (3) Combined hemorrhagia and urticaria, which includes Henoch's purpura and purpura rheumatica. In this group the most prominent symptoms are due mainly to the urticarial factor, but this factor does not cause any drain on the blood-forming organs and the spleen does not enlarge. There is no constant characteristic change in the blood cells. No sharp dividing line separates the hemorrhagic diathesis from splenic anemia, but Banti's disease and hemophilia are separate entities. In hemophilia there is the lengthened coagulation time and the normal platelet count. Purpura does not occur in hemophilia. Banti's disease terminates in hepatic cirrhosis and ascites, neither of which occurs in the hemorrhagic diathesis. In Banti's disease there is no purpura. In severe cases of the hemorrhagic diathesis splenectomy is indicated if anemia is advancing and leucopenia is present in addition to a low platelet count, but is contraindicated unless the platelets are diminished in number. Blood transfusion should in all cases be performed before operation for splenectomy. No definite results can be ascribed to the use of hemostatics or calcium salts. Intravenous injections of adrenaline 1 in 1000 have been known to

check the hemorrhages in children, and success has been reported from the injection of t.a.b. vaccine.

Treatment of Malignant Tumors with Radioactive Bismuth (Radium E).—H. Kahn, writing in the *Deutsche medizinische Wochenschrift* of December 12, 1930, says that bismuth is the only heavy metal that is deposited electively in tumor cells, and the only one that produces improvement without considerable toxic secondary effects. Injections of bismuth, however, even when combined with irradiation, have had very little permanent effect. Experiments were therefore tried with a view to strengthening the effect of inactive isotopes afterwards by active ones, that is, instead of irradiating from outside, attempts were made to transfer the irradiation into the tumor cells themselves. To do this an active bismuth isotope was necessary, and since all other bismuth isotopes are very short-lived, radium E was practically the only radioactive substance through parenteral administration of which one might hope to influence the tumor cells without doing injury to the body cells. As was expected, injections of bismuth preparations containing radium E into mice with inoculation carcinoma resulted in 6 per cent of the injected mass being found in the tumors. On an average 18 times as much radium E was found in the tumor as in a corresponding amount of normal tissue. Similar results were observed in human beings in whom demonstrations could be made after operative treatment. The author's radiograms showed the same selective deposits even more clearly, when microtome sections of tumors and organs were laid upon a photographic plate in the dark-room. Radioactive bismuth is excreted chiefly through the kidneys, and but little through the liver and intestines, which organs accordingly exhibited far stronger concentrations of active bismuth. But unlike most other radioactive substances, especially mesothorium, radium E has no affinity for the reticuloendothelial system and the spleen. Hence no appreciable injury has been observed after injection of radium E, despite the fact that the equivalent of 3 mg. radium per dose has been injected intravenously. It is too soon as yet to express a judgment as to the value of therapeutic attempts with radium E in connection with human tumors.

Duration of Breast Feeding: A Comparative Study.—Joseph Garland recalls the statement of enthusiasts that 99 per cent. of modern mothers can and should nurse their infants. This, he finds is not the situation in and around Boston. An increasing number of mothers are temperamentally incapable of nursing their young for any material length of time, and still greater numbers seem to be physically incapable of it even after a conscientious effort has been made. It must be generally acknowledged that bottle feeding no longer entails the dangers which were formerly associated with it, for if it is carried out properly, its success so closely approximates that of maternal nursing that the results are practically indistinguishable. Garland studied two groups—a group of private patients and a clinic group—of 200 cases each, to ascertain the average duration of breast feeding in different types of patients, and, as far as possible, the nursing schedule which seemed to be most successful in promoting nursing. The major reason for weaning was found to be an insufficient amount of milk in both groups, despite special efforts made to continue nursing. Electric and water pumps, while effective, were rarely tolerated for any great period of time, and the technique of manual stripping was firmly rejected by the majority of those by whom it was attempted. Breast feeding was, in general, less successful and earlier terminated in the private case group. Only 27 per cent. of the mothers in the private patient group nursed beyond an arbitrary period of five months, as compared with 51.5 per cent. of the clinic mothers. Nearly the same number in each group made a practical failure of nursing, discontinuing the effort after a month or less, 52 in the private case group and 50 in the clinic group. The evidence seemed to be in favor of the four-hour schedule in the private case group, but was not well carried out by the clinic group. The distinct impression gained is that success in nursing depends more upon the ability and desire of the mother than upon any arbitrary factor such as a defined schedule of nursing hours. If any set rule should be established it is this: that every mother, *other things being equal,* should be encouraged to nurse her infant for a reasonable length of time; that she should be instructed in methods of increasing and continuing her supply of milk, and that the duration of nursing should be left to the discretion of the individual physician.—*New England Journal of Medicine,* December 25, 1930, cciii, 26.

The Recognition of Latent Thrombosis.—The increase of thrombosis and embolism since the War points, in the opinion of v. Hagen, to the need of utilizing every means of diagnosis and of piecing together small bits of testimony to insure the early detection of danger. In an illustrative case a patient who had been allowed to sit up in bed on the third day following a myomectomy suddenly devel-

oped severe pain in the right shoulder, which persisted 3 or 4 days, then disappeared. The patient was allowed to get up on the 10th day after operation, but died suddenly on the 13th day without the least premonitory symptom beyond a temperature of 37.7° C. (100° F.) taken 3 hours before. It was later recalled that she had complained of extreme sensitivity of the skin over an area extending from the top of the shoulder to the deltoid tubercle. The case was therefore one of a so-called Head's zone, which corresponded to the nerve supply from the 3d or 4th (or 5th) cervical segment, in which the visceral sympathetic nerves of the lungs debouch. In such a case the transfer of the irritation from the sympathetic tracts into the cerebrospinal nerves is made in the spinal cord itself, constituting the so-called viscero-sensory reflex. There is no doubt that an embolus had lodged in the right lung on the 4th day after operation, the origin of which was in a thrombosis of the pelvic veins. It was small enough to pass through the heart and to arrive in the right upper lobe without causing any local pain in the lung but, instead, projected a sensitivity into the entire cutaneous region corresponding to the common spinal segment. This viscero-sensory reflex must have pointed to an embolic lung affection on account of its sudden appearance, and should have been regarded as a strict indication for a stay in bed. While the coincidence of a latent thrombosis with a Head's zone is not an everyday observation, it teaches that if such a zone appears after an operation or in the course of a chronic confinement to bed, one should think of a possible thrombosis which has caused what might be called a "still" embolism in the viscus corresponding to the cutaneous zone.—*Münchener medizinische Wochenschrift,* November 14, 1930.

The Toxicology of Thallium.—After reviewing the literature of the pharmacology and chemistry of thallium, G. Roche Lynch and J. M. Spencer Scovell report three cases of fatal poisoning in three brothers. The three boys, aged 10, 7, and 5 years, as the result of a mistake in making up the prescription, received 39, 36 and 28 grains of thallium, respectively. The intention was to give the two eldest boys 3.9 grains and 3.6 grains, while the youngest was to have had 2.8 grains, *i.e.,* 8.5 mg. per kilogram of body weight. The two eldest boys died on the following day, the youngest on the third day. From the post-mortem examination it appears that in large toxic doses thallium acts as a mild irritant to the stomach. It poisons the more highly specialized cells of the body, causing marked fatty degeneration in heart and liver and necrosis in the kidney. These changes are rather like those seen in the phosphorus group of poisons, but differ in that the fatty degeneration is most marked in the myocardium. In this respect thallium seems to be unique. After a review of the literature of fatal cases of thallium poisoning the authors conclude that thallium acetate should not be used as an ordinary routine treatment for ringworm of the scalp. The drug is a highly toxic substance showing a marked similarity to lead, both in its chemistry and in its toxic symptoms, and the far-reaching effects of the poison are much greater than is generally supposed. It has a definitely selective action on all forms of nervous tissue, and it has been demonstrated that even in infinitesimal doses, it causes slight degenerative changes in the brain cells of rats. It is therefore most unlikely to leave the human brain entirely unchanged; it seems impossible to be certain that it does not hinder further brain development. The margin between an epilating and a toxic dose is extremely small and allows for no idiosyncrasies, whereas with the *x*-rays the dosage is very accurate, and if a mishap occurs it is at least local.—*The Lancet,* December 20, 1930, ccxix, 5599.

A Method of Reduction and Fixation of Pouteau-Colles's Fracture.—Raoul Hoffmann outlines in the *Schweizerische medizinische Wochenschrift* of November 15, 1930, his treatment of Colles's fracture, which consists in reduction by mechanical traction under local anesthesia, and maintenance of the parts in physiologic position with *direct* fixation of the fragment. The patient sits on a low chair with his entire arm extended on a table the top of which is on a level with his shoulder, so that the axilla, supported against the table edge, furnishes counter-extension. *No steel rod need be* passed across the metacarpals. All that is needed is the familiar 4-tailed bandage, with strips 75cm. long and 10 cm. wide, put on in imbricated manner over the carpus and metacarpus, after which a few turns of an ordinary bandage are applied, making a homogeneous support that holds very solidly to the member, from which no amount of force can displace it. A cord passed over a pulley or bottle with a weight of 10-15 kg. at its other end makes mechanical traction upon the hand and wrist, and overcomes all resistance of muscles and ligaments in 10-15 minutes at most. A final blow with the thumb upon the back of the epiphysis will complete the reduction if it has not occurred spontaneously. Usually the fragment is so well restored to place that all it has to do is to stay there, and the type of splint matters little. Hoffmann uses a Hülsemann splint of flexible

steel, the convex surface of which is adapted to the middle of the palmar surface of the forearm, where it is held in place by two straps, one at the upper end of the forearm and the other exactly at the level of the broken fragment, thus constituting a lever of the first rank. A projecting piece of splint maintains the wrist and metacarpus in physiologic position, elevated at an angle of about 20° in dorsal extension, with the fingers entirely free for use from the first hour. After a week, or two weeks at most, the splint is removed daily for the mobilization of the joint.

Pleural Effusions in General Practice.—W. Arnott Dickson, writing in the *British Medical Journal*, December 20, 1930, ii, 3650, expresses the opinion that in the examination of cases of chest disease the possibility of effusion is not sufficiently kept in mind, and that there is a lack of clear teaching as to what should be done when effusion has been found. Excluding effusion which is a sequel of injury to the chest wall, and which is really surgical, he discusses two varieties: (*a*) clear; (*b*) thick. A transudation of clear fluid of low specific gravity, noninflammatory in nature, and associated with edema elsewhere is most frequently found in heart disease. It should be removed when it is causing distress, and as often as is necessary. A clear effusion, often coming on insidiously, and without evident cause, the so-called *primary* or *idiopathic* effusion is usually due to pulmonary tuberculosis. This type of effusion often goes undiagnosed because of the erroneous belief that breath sounds are invariably absent over the fluid. The golden rule is: when in doubt, put in a needle. In the treatment of a tuberculous effusion, the fluid itself, if at all possible, should be left severely alone, and the patient should be treated for pulmonary tuberculosis in a sanatorium. Should simple aspiration be resorted to, it is best not to withdraw more than a pint at a time, and the actual withdrawal should occupy ten minutes. In thick effusions the presence of blood has no real significance. The immediate requirement is to establish the identity of the organism responsible for the pus. In pneumococcal empyema, in the presence of a high pulse rate after the crisis the exploring needle should be used as a matter of routine. The critical question in connection with operation is, "Has the pneumonia subsided?" Until this can be answered in the affirmative, open operation should be deferred. The pneumococcal empyema, with its creamy yellow pus, found about four weeks after the onset of the illness, should be handed over to the surgeon at once for adequate drainage, which usually means resection of a rib, under local anesthesia. The streptococcal cases must on no account be operated upon at once, or the chances of recovery are immediately reduced. The chest must be aspirated as required to reduce pressure, over a period of about three weeks, until the fluid becomes frankly purulent and adhesions have formed.

Vasomotor Rhinitis.—Joel J. Pressman suggests that the term "turgescent rhinorrhea" be used as a substitute for the term "vasomotor rhinitis," since our lack of knowledge of the physiology does not warrant the use of the latter. There is evidence that the condition may be glandulomotor or lymphaticomotor, as both glands and lymphatics are supplied by sympathetic nerves. In practically all cases in the group turgescence and rhinorrhea are constant factors. The etiology can be allergic or nonallergic, and in each case it is necessary to determine which is the causative factor. Certain local nasal conditions, such as deviated septa, polyps, and sinus infections are often present in turgescent rhinorrhea and may represent either the primary etiology or be a complication of an allergic state. The etiology cannot be determined by therapeutic trial. The criteria by which we can distinguish allergic from nonallergic turgescent rhinorrhea are the history, examination of the nose, study of nasal secretions, histologic studies of the nasal mucosa, and the determination of sensitivity to foreign proteins. Allergic rhinitis gives characteristic histopathological changes, which may be markedly altered by secondary suppuration. In uncomplicated allergic rhinitis there is marked and consistent subepithelial infiltration of eosinophiles, dilatation of the glandular structures, intercellular edema and at times dilatation of the vascular channels. With a superimposed suppurative rhinitis the microscopical picture cannot be distinguished from that of an infectious rhinitis in which allergy plays no part. There is no reason why the rhinologist should not follow the fruitful expedient of the general surgeon and attempt to establish the diagnosis by performing a biopsy in all cases of doubtful etiology. Allergic studies should be carried out before attempting to treat any case, even though it may appear that local conditions are the etiologic factor. Exception may, however, be made when, for example, a large polyp is present or there exists a chronic extensive sinus infection which will eventually require surgical treatment. Because of the frequency of complications, it is almost obligatory on the part of the allergist to subject each case of allergic rhinitis to a thorough and complete otolaryngological examination.—*Laryngoscope*, December, 1930, xl, 12.

LEGAL

A JUST CENSURE

By Lorenz J. Brosnan, Esq
Counsel, Medical Society of the State of New York

We are all familiar with the fact that there are certain lawyers who, in representing a plaintiff in a lawsuit, will endeavor to force a settlement from the defendant by threats of criminal prosecution if a settlement is not forthcoming. So far as the ethics of the situation are concerned, it makes not the slightest difference whether the lawyer follows up the threat by a criminal prosecution. A member of the Bar who indulges in practices of this kind reflects discredit not only upon himself, but upon the profession of which he is a member.

A short time ago there was brought before one of our Appellate Courts a disciplinary proceeding initiated by the local Bar Association in connection with the activities of a certain lawyer who in a civil case threatened a defendant with criminal prosecution. Although no criminal prosecution was attempted, the Appellate Division severely censured this attorney for his misconduct.

The letter written by the lawyer against whom disciplinary proceedings had been taken in this matter read as follows:

"In behalf of my clients, I instituted action against you for the recovery of damages to my client's automobile and damages for personal injuries sustained by them as a result of an accident wherein your taxicab collided with an automobile operated by my client. My process servers made many attempts to effect service upon you but without success. I was, therefore, compelled to procure an order of the court permitting service of the process upon you by substitution.

"Up to the present time I have not received an answer to the summons, and I am, therefore, in a position to enter judgment against you by default. *If I am put to the trouble of proceeding against you personally on the judgment referred to, I will be compelled to institute criminal proceedings against you for failing to cover your taxicab by proper insurance policy under the law.* I have been more than lenient with you and will refuse to tolerate any more of your nonsense.

"I, therefore, trust that you will see the advisability of taking this matter up with me immediately upon the receipt of this letter.

"This is my final notice."

The lawyer admitted writing the letter, but claimed that the letter was written with a view to getting the defendant, a taxicab driver and owner, to turn the matter over to his insurance company, the lawyer being of the belief that the owner was covered but had simply neglected to refer the claim to the insurance company. His interpretation of the letter was that it was simply a notice that prosecution for the violation of a penal statute would follow if it developed that there was no insurance. The Appellate Division, however, in its opinion disposed of this explanation in the following language:

"We think the letter presents the alternative of payment or criminal prosecution."

The learned Referee to whom this matter was in the first instance referred reported to the Court as follows:

"Neither the motive of the respondent in the present proceeding, nor the outcome, can alter the principle involved. There should be no confusion in the mind of any lawyer as to the distinction between criminal and civil proceedings. The former are brought for the protection of society, and the latter for the enforcement of individual rights. It is within the province of any citizen to bring violations of the criminal law to the attention of the appropriate authorities. Had respondent, whether in proceedings against B, after a default judgment, or in any other manner, found that he was uninsured, he might properly have caused charges to be preferred against him. The question here is whether a member of the Bar may ever, prudently and properly, make demands of a defendant in a civil suit coupled with threats of criminal proceedings unless those demands were complied with. Of course, differences in degree are to be recognized. It is one thing to threaten criminal proceedings in connection with the assertion of certain claims, and it is another thing actually to institute such proceedings. So also it may be one thing to make such threats, unless damages are paid or money demands complied with, and another thing to couple those threats with lesser demands. The precise threat in the letter under consideration is found in the following passage:

"'If I am put to the trouble of proceeding against you personally on the judgment referred to, I will be compelled to institute criminal proceedings against you for failing to cover your taxicab by proper insurance policy under the law. I have been more than lenient with you and will

refuse to tolerate any more of your nonsense. I, therefore, trust that you will see the advisability of taking this matter up with me immediately upon receipt of this letter.'

"It is true that B could turn aside the threat, either before judgment or after judgment, if he was in point of fact insured. In such event the threat could have no terror for him. But it seems equally true that in case he had not taken out insurance or had permitted it to lapse or to be cancelled, he was threatened with criminal proceedings which he could only avoid by making adjustment with respondent. It is also true that respondent obtained the legitimate result which he claims to have been seeking. It still remains a question whether he used legitimate means to do so. There is a threat in the letter which cannot be read out of it."

In severely censuring the lawyer in question the Court said:

"We are of the opinion that the letter in question was improper, and that in writing and sending it respondent was guilty of unprofessional conduct. This court has heretofore expressed its disapproval of using threats of criminal prosecution as a means of forcing a settlement of civil claims. Thus in . . . (citing a case) an attorney was censured for having written a letter demanding the return of an engagement ring and other valuables, with the statement therein that the recipient of the letter was liable to criminal prosecution, but that if she returned the property no further proceedings would be taken. In . . . (citing a case) an attorney was censured for having written a letter in which he wrote that unless the person against whom a claim for damages for personal injuries showed 'some substantial evidence' of his willingness to compensate the client for her injuries, 'I shall have no other alternative but to immediately criminally prosecute you for assaut against my client.' Respondent in that case had endeavored to get the addressee of the letter to sign an affidavit admitting that he had committed a misdemeanor in not stopping his car after the accident.

"Where the threat to begin criminal proceedings is followed by the actual institution thereof the offense is still more serious, and in . . . (citing a case) an attorney guilty of making such threats, followed by an attempt to secure the indictment of the person threatened, was suspended for one year only, in view of his youth and inexperience. In its opinion the court, through Presiding Justice Ingraham, expressed the opinion that 'a lawyer is never justified in using a criminal proceeding to collect a civil debt or enforce a civil right.'

"Respondent has been guilty of a violation of the principle which condemns any confusion of threats of criminal prosecution with the enforcement of civil claims. For this misconduct he should be severely censured."

The Appellate Division in its opinion in this case, in no uncertain terms, places its stamp of disapproval upon practices of this character. We believe that every lawyer who has a proper regard for the obligations that attach to his office will agree that the severe censure visited upon the lawyer in question by the Court was entirely justified.

ALLEGED NEGLIGENT TUBERCULIN INJECTIONS

In this case a young woman called at the office of the defendant, a physician and surgeon, specializing in eye diseases. She complained of soreness in the left eye and gave a history of recurrent attacks of inflammation in her eye for a period of seven years following an attack of ear infection. The doctor advised that she should submit to a series of treatments consisting of tuberculin injections. Eight injections of progressively increasing strength were given her and then she failed to return for further treatment. These injections were each given subcutaneously in the arm, and all care was taken in each instance to sterilize the needle. The fluid injected was prepared by the house surgeon from ampules furnished by the City Board of Health.

A suit was instituted against the doctor who examined her and it was claimed that the patient did not at any time have an ulcer of the eye, but had merely what was termed a "squint" and that the injection given was improper treatment for the condition. The plaintiff further claimed that as a result of these allegedly improper injections a rash had broken out all over her body and caused her great discomfort and suffering.

A physical examination of the plaintiff was had and an extensive skin disease was found. The skin in large areas was scaly and thickened, with reddish blotches. It was, of course, asserted that the condition had been much worse prior to the examination and subsequent to the injections. The condition seemed to the examiner to be Lichen, but there was no symptom to indicate a causal connection with any act for which the defendant was responsible.

The case came on for trial in its regular order, and when it was called the defendant was ready to proceed but the plaintiff was not. A motion was made to dismiss the action and was granted, thereby terminating the matter in the doctor's favor.

NEWS NOTES

DUTCHESS COUNTY PUBLIC HEALTH AND PUBLIC RELATIONS

Read at the Annual Meeting of the Dutchess-Putnam Medical Society, January 14, 1931.

The Committee on Public Health and Public Relations begs leave to offer the following report of its activities for the past year.

Three years ago, this Committee was appointed by your Society and set about to do its work as outlined by the State Committee of Public Relations, and during those years a good deal has been accomplished to bring about the co-relation of the Medical Society and the various agencies doing health work; and in the minds of your Committee the accomplishments have been due entirely to the willingness on the part of the laity to co-operate with their medical brethren.

There has never been a time when everyone who is at all interested in the promulgation of public health has refused to put their shoulder to the wheel and assist in every way possible the various ideas and plans which the Medical Society has thought wise; and at the same time your Committee knows of but one instance, which will be discussed later, where the opinion of your Committee was disregarded.

It is fitting at this time to extend to the Dutchess County Health Association, the heartfelt thanks of the Society for its earnest co-operation and support in every effort to bring about a realization of the aims and principles of this Committee. Particularly do we wish to thank Miss Dorothy Carter for her loyalty and untiring efforts in behalf of public health, and while expressing deep regret at her departure from our midst to a field where her usefulness will be much appreciated and of benefit to everyone. We feel that her successor, Miss Frances Clark, is well qualified to take on the mantle of responsibilities as has been shown in her desire to continue the assistance which is so greatly needed for the successful culmination of the important projects which now confront us all.

One year ago, the Committee made certain recommendations, which were confirmed by the Society, and in this connection it may not be amiss to mention that several have been carried out.

The campaign of toxin-antitoxin against diphtheria has been continued by the individual members of the society, not with any widespread publicity, as in former years, but with quiet, continued work among each one's clientele, with the result that our County now is not in the laggard class in this respect. The examination of the school child has been somewhat modified. More stress has been laid on such examinations by the family physician, with the result that many children have been thus examined, not with any better results, but with more comfort to the little patients and a great satisfaction in the fact that State medicine is not advancing at the alarming rate some would think.

The tuberculosis prevention has been advancing and at the present time x-rays are being taken in many instances, among the schools, to determine the incipient case. This should be encouraged with the view to lowering the mortality of this dreaded disease in the age group, which is greater than all others.

The pre-natal clinics have been continued and increased, and it is pleasing to note that the interest and attendance is more than in previous years, which is gratifying to all who are concerned in the reduction of maternal mortality.

The pre-school clinics are progressing and your committee has in mind, in response to a request from the Commissioner of Health of the State, to inaugurate more of these clinics during the coming year, with the idea that the entire county may be covered, and no child of tender years be prevented from regular routine physical examination. Only by means of such efforts can the infant mortality be reduced to a point where we can point with pride at our record.

All of these efforts have been possible only with the full co-operation of the medical profession and the various health organizations, and the willingness on the part of both to work together for a common cause.

The Board of Supervisors has been particularly gracious in appropriating money for honorariums to the physicians conducting these various clinics and for increasing the number of public health nurses in our county.

They are to be thanked and commended for their interest in public health and prevention of disease and your committee knows of no solicitations, which have been shown necessary, being refused.

The City of Poughkeepsie has created a Department of Child Hygiene with a director, and it is hoped that this will be fruitful in bringing about the desired results, namely, the

prevention of the unnecessary large sacrifice of human life during the tender years of infancy.

One year ago, the committee recommended that this Society endorse the plan of a County Health Department for Dutchess County, and at the time it was considered by the Board of Supervisors, by the appointment of a committee to study the situation. A careful review of conditions in this county was made by your committee and it was deemed expedient to defer, for the time being, any efforts to bring about the establishment of this department, and while your committee has not changed its ideas on this subject, it does feel that the postponement of its inception, for a short while, will work to better advantage to the profession, to the laity and to the powers which must be financially responsible for its completion.

In this connection, your committee feels that a few words of criticism may not be amiss.

The State Department of Health, through its official representative in this district, has been most urgent in its efforts to bring about the establishment of the county health department, contrary to the advice of this Committee and other members of the profession, and the attitude by him has been such, that it is feared the establishment of such a department has been longer postponed than would have been necessary.

One of the first principles evolved by the State Committee on Public Relations, was the co-relation of the profession with the various health agencies, notably, the Department of Health, and it is to be regretted that this difference of opinion has arisen between the profession and the one agency which should be the first to co-operate.

In the words of Elbert Hubbard "Any system can be defeated by one single man who places himself out of harmony with it."

The unemployment situation with its naturally decreased incomes, and the relation of our profession to this condition, was presented to the society for consideration and referred to this committee.

After very serious thought your committee feels that any action of a definite nature would not be productive of the results desired. While, at the present time, so much is being written on the high cost of medical care, including physicians' fees, which are receiving a great deal of criticism, this in the minds of the committee is erroneous since it has been estimated that only about twenty per cent of such costs goes into the pockets of the medical man. We feel that the problem is an individual one, to be settled by each member of the profession, either by a reduction of fees, extension of credit, or whatever contribution he may choose to make to relieve the situation.

Article X, Section 83, of the Public Welfare Law, reads: "The Public Welfare District shall be responsible for providing necessary medical care for all persons under its care, and for such persons otherwise able to maintain themselves, who are unable to secure necessary medical care. . . . Such care may be given in dispensaries, hospitals, the person's home, or other suitable place."

From the beginning of time almost, down to the present, physicians have been giving of their services to deserving cases with no thought of recompense, and they have given such services gladly, with the only thought of reward being perhaps an extra star in that crown for those to whom it may be said "well done," etc. Now the great State of New York has seen the light of day, and enacted a law which makes it mandatory for the doctor to receive compensation for the work he does among the wards of the various welfare districts. So far as can be learned, this has been taken care of in those cases cared for in their own homes, but when it comes to hospital care, nothing has been done and the rules of most hospitals prevent a doctor charging for cases he cares for in a general ward. There is no reason in the world why a physician who gives his services to those who need them, should not be paid, and it is now the time for us to get together in some concerted action, to the end that the *tradition,* so long prevalent that doctors do not need to charge for their services in needy cases, be broken down and the welfare district be reminded of their duty.

Just how this should be done, is not at present pertinent to this report. Whether the matter is one of hospital management of the ward cases, or otherwise, your committee does not feel competent to pass on at the present time.

It is recommended that this be given careful study by this society, either through a special committee or this committee, if you so desire, with the idea of bringing about some concrete plan whereby physicians may receive a fair compensation for their services. "A laborer is worthy of his hire," and the time has arrived for the physicians to come into their own.

William Gerry Morgan, President of the American Medical Association, said in a recent address: "The popular misconception has arisen that the doctor's services are included in the hospital's service and that one bill covers both. On the contrary, the hospital in no sense provides the services of the physician

who treats the patient there. The services are not the hospital's to provide. The physician is no more obligated to provide for the care of the indigent sick than his fellow citizen."

This briefly covers the activities of the committee during the past year. We feel that our efforts have not been entirely in vain, our relations have been pleasant and each member of the committee has done whatever he could to promote good feeling between the profession and other agencies. The final sentence in the report of the Dutchess County Health Association, to this committee, is timely at this time. "Along any of the lines of the Association's work, we would welcome suggestions from you. We are very anxious to cooperate with you in furthering the health work of Dutchess County in any way we can"

Your committee feels the profession has reached a point in its existence, that requires constant watching and has shown by its attitude that they are the leaders in matters concerning public health.

Dr. Ochsner of Chicago, has said, "The longevity, health, efficiency and happiness of the people, depend more upon the integrity, ability and industry of its medical profession than upon anything else."

This report would not be complete without extending to the members of this society the sincere thanks of the committee for their loyal support. It would have been impossible for this committee to have accomplished anything without the backing the society has given it, and to our successors we offer the same efforts that have been afforded us.

In the words of Disraeli, "The public health is the foundation upon which rests the happiness of the people and the welfare of the nation."

JOHN A. CARD, *Chairman.*
C. KNIGHT DEYO,
WILLIAM A. KRIEGER,

LEGISLATIVE BULLETIN NO. 1

January 20, 1931.

The legislature has begun its regular sessions. There have been quite a few changes in the personnel of the two Houses. Our Public Health Committee has a new chairman in each House. The personnel of the Senate Committee is:

A. H. Wicks (Chm.), J. Griswold Webb, Warren T. Thayer, Perley A. Pitcher, Leon F. Wheatley, Wm. Lathrop Love, John A. Hastings, John T. McCall.

The personnel of the Assembly Committee is:

W. Ray Austin (Chm), Burton D. Esmond, Frank X. Bernhardt, Charles J. Gimbrone, Victor C. Lewis, James R. Stevenson, J. Devillo Pollard, F. Lewis Palmer, George E. Dennen, John A. Devany, Edward P. Doyle, Alexander A. Falk, Christopher C. McGrath.

Both committee rooms are on the fourth floor of the Capitol this year. In previous years they were on the third floor, as many of you will recall. Since the occupacy of the new state office building more space has been made available in the Capitol for the legislative committees.

Senator Pitcher, who was chairman of the Senate Public Health Committee last year, has been promoted to chairman of the Committee on Codes. Dr. Lattin, who was for so many years chairman of the Health Committee in the Assembly, did not return. Mr. Austin, the new chairman, was a member of the committee for a number of years.

Only seven bills thus far have been introduced in which we have a particular interest. Three of these are reintroductions. Mr. Cuvillier has introduced again his health insurance bill—Assembly Int. No. 5; Mr. Vaughan has reintroduced the dog bill—Assembly Int. No. 143; Mr. Horn has reintroduced the compensation bill which he carried last year—Assembly Int. No. 52. Dr. Love has introduced a bill, Senate Int. No. 86, making it a misdemeanor for any person causing one baby in a hospital to be exchanged for another, each newly born baby to be finger printed and tagged and kept in separate receptacle; and and another prohibiting a drug store or pharmacy from selling food to be consumed on the premises, Int. No. 47.

Senator Buckley has introduced a bill authorizing certain child welfare boards to establish vacation camps for children, Senate Int. No. 42.

Mr. Berg, who as Assemblyman has helped us several years in our opposition to the chiropractors, was promoted to the Senate at the last election. He has introduced a bill in the Senate—Int. No. 64—making compensation for any disability not to exceed $25.00 a week.

The attention of the chairmen is again called to the conference which will be held in Albany on Tuesday, February 10th. Already quite a number of chairmen have written us that they will be present. It will help considerably in arranging the luncheon if we know in advance about how many reservations to make.

PUBLIC RELATIONS COMMITTEE

The regular monthly meeting of the Committee on Public Relations was held on the morning of Thursday, January 8, 1931, in the building of the New York Academy of Medicine, at 2 East 103rd Street, New York City, with the following members present:—

Dr. James E. Sadlier, Poughkeepsie, Chairman.
Dr. A. J. Hambrook, Troy
Dr. W. D. Johnson, Batavia
Dr. O. W. H. Mitchell, Syracuse, N. Y.
Dr. George M. Fisher, Utica

The following representatives of the Medical Society of the State of New York were in attendance:

Dr. W. H. Ross, President
Dr. D. S. Dougherty, Secretary
Dr. Charles Gordon Heyd, Treasurer
Dr. J. A. Card, Speaker of the House of Delegates
Dr. J. S. Lawrence, Executive Officer
Dr. Frank Overton, Executive Editor
Dr. T. P. Farmer, Chairman of the Committee on Public Health and Medical Education
Lorenz J. Brosnan, Esq., Counsel

The County Medical Societies of Greater New York were represented as follows:

New-York County:
Dr. DeWitt Stetten
Dr. Frederic E. Sondern

Kings County:
Dr. Walter D. Ludlum, President
Dr. Alfred E. Shipley
Dr. Alec N. Thomson

Bronx County:
Dr. J. H. Gettinger, President
Dr. Irving Smiley
Dr. E. C. Podvin

Queens County:
Dr. A. L. Voltz, President
Dr. Carl Boettiger

The special subject of discussion was the part which the medical profession of Greater New York could take in the work of the general committee on Public Relations. The discussions took the form of diagnosis rather than treatment, as might be expected since this was the first meeting held in cooperation with the Metropolitan societies.

Dr. Shipley of Kings County spoke of some difficulties encountered in the anti-diphtheria campaign. While all the counties were confronted with the same general problems, their details varied in the several counties. The greatest need in the City was that the county societies should realize the elements of the public relations which are common to all. He felt the great difficulty at present is that each county sees a problem as affecting it in a way different from that in which it affects the other counties. He thought that if the five County Societies could be closely organized through proper representatives, such organization might accomplish a great deal under the direction of the State Public Relations Committee.

Dr. Alec N. Thomson, speaking for Kings County called attention to the complexity of medical organization in the large city. In addition to the five county official organizations, there are many unofficial medical groups organized primarily for scientific study; and in addition to these, there are others which have active committees and conferences continually at work and make practically no effort at unification of activity or program. He proposed, for example that the Public Relations Committee can be of great service in supporting local organizations by directing a proper opposition to the extension of free clinics as advocated by the local Committees on Tuberculosis.

Dr. Walter D. Ludlum, President of the Kings County Society, having arrived in the meantime, stated that he thought the greatest handicap the County Societies suffer is in the lack of continuity of elected officers. A man might have a very good program and actively advance it, but at the end of the year he is gone and his successor cannot be expected in every instance to carry forward his program and then a change of administration means not only a change of one man, but of a number. On the other hand, the official and voluntary health agencies have definite and more or less permanent organizations. The Academy of Medicine, likewise, has a more continuous organization and, for that reason, is many times called upon to represent organized medicine.

The representatives from Bronx County spoke as follows:

Dr. J. H. Gettinger, President, endorsed the idea of a closely knit organization representing the five Societies, and pointed out the need and the opportunity of work for such organization.

Dr. E. C. Podvin stated that in his opinion the greatest difficulty in securing the maximum benefit from such an organization is to keep busy men interested. He believes that unless somebody makes it his special business to see that the members to a five county organization are kept intimately informed with things that are happening and with the work that they are expected to do, they will lose interest and not attend conferences. He cited from his own experience how difficult it is to keep interest in such live subjects as tuberculosis. He, however, endorsed most heartily the idea of a five-county organization.

Dr. Irving Smiley, Vice-President, offered the opinion that the public has been getting a wrong impression of physicians' interest in public health. It believes that the average physician is only interested in therapy and not in prevention, and he

felt that to advance our influence we ought to make an effort to correct this impression

The representatives of New York County expressed the following opinions

Dr DeWitt Stetten, Past-president of the New York County Society, agreed that we should make an effort to reestablish confidence in medicine with the public He felt we must not be too dignified and aloof, but must be more willing and ready to cooperate with those who are seeking to advance public health and to do it to an extent in their way He felt that the voluntary agencies may be found very useful and helpful if the proper contact is made with them, and the physicians take pains to inform themselves intelligently on the cooperation they develop with the agency

Dr Sondern stated that the time to do something is when that something is demanded and that the voluntary agencies are successful in their public health activity at the present largely because they are doing what the public feels it needs and that the physicians are making a mistake by not making similar use of the demand He said we cannot expect to accomplish much by theorizing, but we must take an active advantage of the demand when it exists He attributed our apparent apathy to a defect in our education That there should be so much discussion with regard to the inability of a large portion of the public to provide adequate medical care is largely due to lack of proper provision on the part of the medical men themselves He thought the County Societies might do more toward educating their members on the general problem of public relations and modern duty

Dr Carl Boettiger, Chairman of the Queens County Committee on Public Relations, reviewed the work that his committee accomplished in the last year It established a contact with all of the voluntary agencies and found such procedure very fruitful By experience he learned that the voluntary agencies are very grateful for the aid they received from his committee, and without hesitation returned, seeking twice as much assistance His committee has arranged to have a physician included in the membership of every voluntary agency working in his city In the near future there will be a general meeting of all voluntary agencies and the Public Relations Committee of Queens County, to devise a program of activities for the coming year

Dr George M Fisher, of Utica stated that he believed the task of organizing the five counties was so great that it could not be accomplished except by the full time services of a physician who could represent the five counties and would have time to make a careful study of local problems Physicians are too busy to volunteer the amount of time that will be required for a task as great as this

Dr O W H Mitchell, of Syracuse stated that his point of view was likely to differ from what had already been expressed, because he is a school teacher and engaged in training medical students He feels that more attention must be given to the proper training of medical students if we expect to have the young men coming out, take an advanced position in the promotion of public health activities

Dr John A Card spoke of some of the difficulties which the Dutchess County Medical Society was having in carrying out its plan for establishing a county health department

Dr W H Ross, President of the Medical Society of the State of New York spoke of the construction work being done by the State Health Commission appointed by Governor Roosevelt, and said that many health bills would probably be introduced in the Legislature this winter as the result of the investigations of the Commission (See this Journal of January 15, page 106)

The following resolution, proposed by Dr Ludlum, was unanimously adopted

"It is recommended to the State Committee on Public Relations that it appoint a committee which in operation may act in an advisory capacity with the local Five County Committee

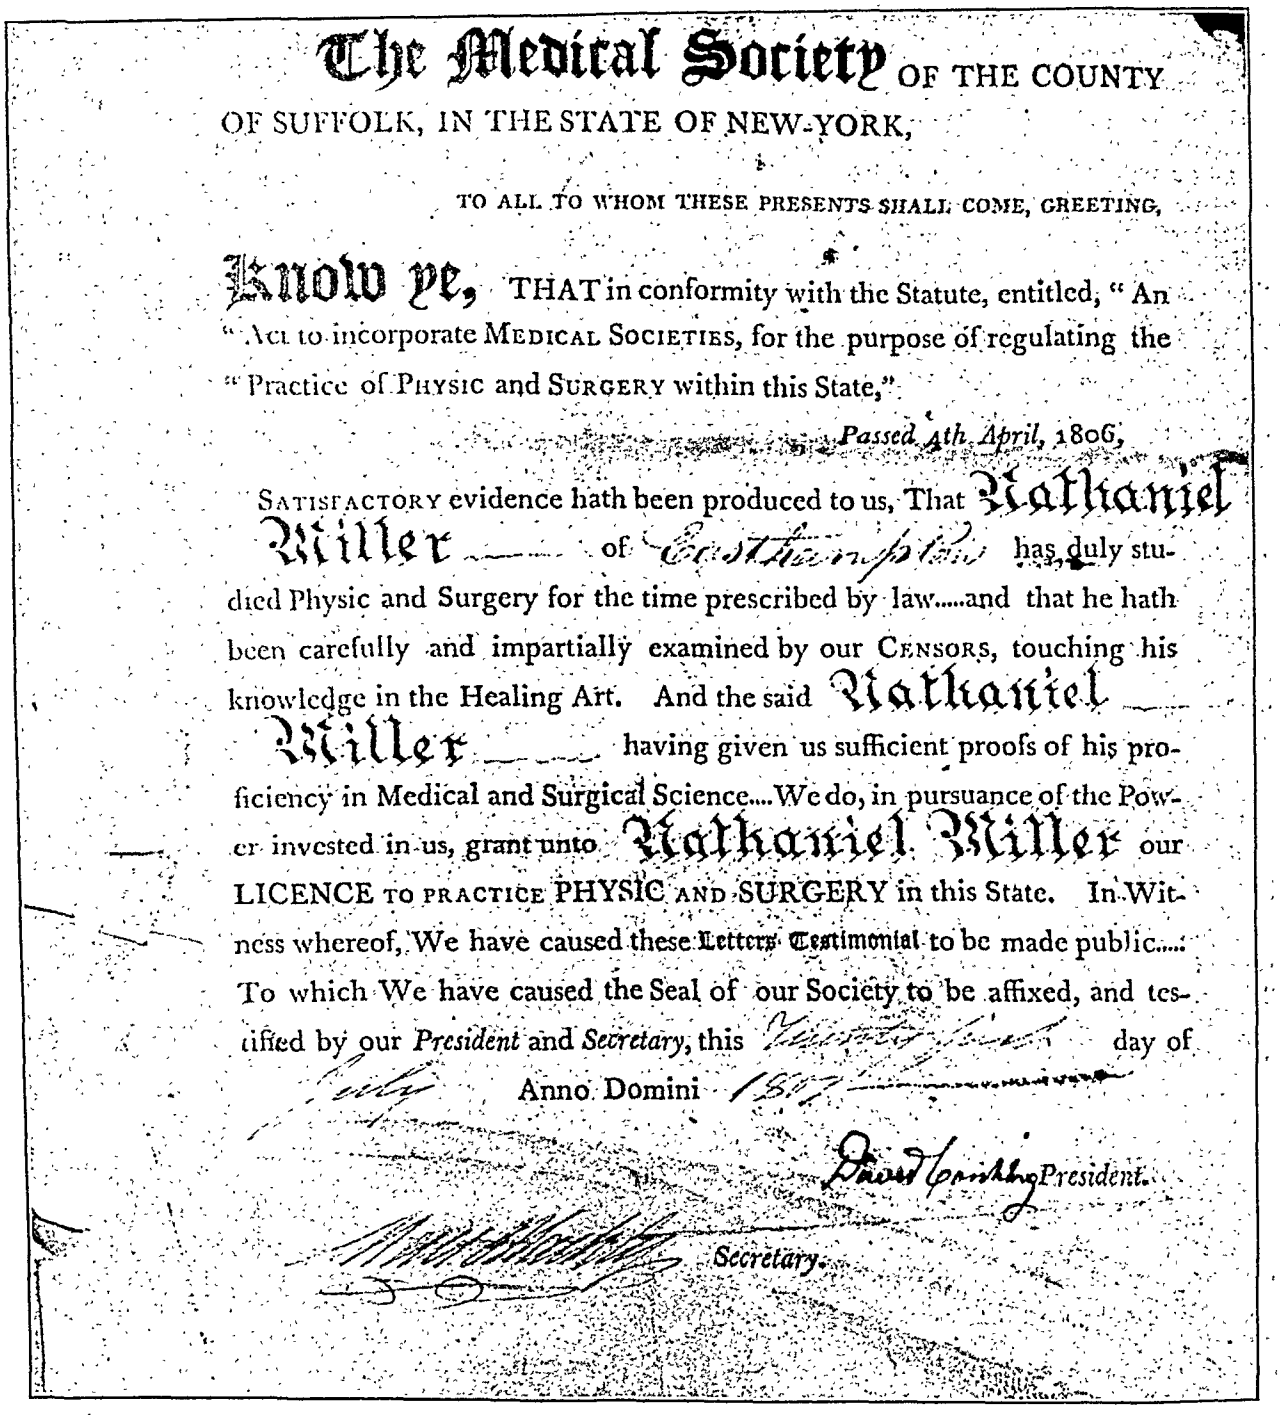
REGULATIONS ON PHYSIOTHERAPY

At the meeting of the Board of Regents held November 21, 1930, a Regulation of the Commissioner of Education was approved by the Board of Regents to govern that part of section 1262 of the Education Law, reading

"A license to practice physiotherapy shall not permit the holder thereof to administer drugs or to practice medicine as defined in section 1250 of this article except to treat diseases under the supervision of a duly licensed physician"

The Regulation is as follows

"Registered Physiotherapists shall keep a written prescription signed by a licensed physician for each patient given physiotherapeutic treatment The prescription shall state diagnosis and the type of treatment ordered Such records shall be open to the inspection of the Department of Education at all times"



The practice of registered physiotherapists is governed by this Regulation

Practicing physicians are requested to cooperate in the enforcement of this regulation by giving such written prescriptions in all cases referred to Registered Physiotherapists for treatment

HAROLD RYPINS M D *Secretary*
New York State Board of Medical Examiners
January 8, 1931

LICENSE FROM THE SUFFOLK COUNTY MEDICAL SOCIETY IN 1807

The Suffolk County Medical Society was organized on July 22, 1806; and just one year later it examined Dr. Nathaniel Miller, and give him the license which is here reproduced. The license was signed by the President, Dr. David Conkling

The Medical Society OF THE COUNTY OF SUFFOLK, IN THE STATE OF NEW-YORK,

TO ALL TO WHOM THESE PRESENTS SHALL COME, GREETING,

Know ye, THAT in conformity with the Statute, entitled, "An "Act to incorporate MEDICAL SOCIETIES, for the purpose of regulating the "Practice of PHYSIC and SURGERY within this State,"

Passed 4th April, 1806,

SATISFACTORY evidence hath been produced to us, That Nathaniel Miller of Easthampton has duly studied Physic and Surgery for the time prescribed by law.....and that he hath been carefully and impartially examined by our CENSORS, touching his knowledge in the Healing Art. And the said Nathaniel Miller having given us sufficient proofs of his proficiency in Medical and Surgical Science....We do, in pursuance of the Power invested in us, grant unto Nathaniel Miller our LICENCE TO PRACTICE PHYSIC AND SURGERY in this State. In Witness whereof, We have caused these Letters Testimonial to be made public.... To which We have caused the Seal of our Society to be affixed, and testified by our *President* and *Secretary*, this [illegible] day of July Anno Domini 1807

David Conkling *President.*

[illegible] *Secretary.*

of Riverhead, and the Secretary, Dr. Moses Blatchley, of Huntington.

Dr. Miller was born in Easthampton in 1784 but practiced medicine in Brookhaven until his death in 1863. He was President of the Suffolk County Medical Society in 1832, when it licensed Dr. George L. Huntington of Easthampton, one of the original observers of Huntington's chorea. He was a corpulent gentleman of the old school, and was slow moving as befitted the dignity of the community doctor. Yet he was prosperous in business, and was active in civic affairs. His mahogany medicine case, as large as a dress suit case, is deposited with the Suffolk County Historical Society in Riverhead.

PHYSIOTHERAPY IN ULSTER COUNTY

The Ulster County Medical Society appointed a committee on Physiotherapy, consisting of Dr A. S. Keefe, Chairman, Dr. O. DuB. Ingalls, and L. Hugel, all of Kingston. This committee made a report on October 8, 1930, setting forth the activities of the physicians of Ulster County along the lines of physiotherapy and allied methods of treatment. The committee secured data from two groups,—those living outside of Kingston, and those living within the city.

Group Outside of Kingston—Reports were obtained from 15 out of the 30 physicians to whom blanks were sent. The number of those using each form of physical therapy was as follows:

Thermal. Conductive heat; poultices, hot water bags, douches, hot and cold packs each 14; baths 11; sprays 9. Convective heat, radiant super heat, electric coils 3; daylight lamps 5; ovens 5

Chemical. Ultra violet light 9; x-ray 5; radium 2; infra red light 5.

Mechanical. Massage 10; manipulation 7; mechanotherapy 3; mechanical vibration 1.

Electric. Galvanic 4; sinusoidal 2; faradic 3; diathermy 7; static 1.

We feel, though the above group is small, that it shows a keen appreciation of the value of physiotherapy, for there is not a single form of physical means in the above classification but what one or more doctors are employing it in their practices. That is, indeed, a very fine showing.

Group in the City of Kingston—Information was obtained from 26 of the group as follows:

Thermal. Conductive heat—poultices, hot water bags, baths, sprays, hot and cold packs. All members of the group use all or nearly all of this form of physiotherapy, no particular equipment being required, except for baths and sprays.

Convective Heat—Radiant super heat, daylight lamps, 3 or 4 doctors; ovens 10 or more.

Chemical. Ultra violet lights are used by 4 or 5 physicians; x-ray 1 or 2; infra red lights 5 or 6, carbon arc lights 3 or 4. There is but one of the water cooled type of ultra violet light, in the city. Three doctors are using radium.

Mechanical. Massage and manipulation, practically all of the group use one or both forms, no special equipment being required. These two items are really a part of mechanotherapy. However, in this latter item it was intended to include such special equipment as would be called for in mechanical massage, kneading, and exercises; and various other apparatus, practically all of which get back to the same idea we started with, massage and exercise. No individual in this group is so equipped.

Electric. Galvanic, 5 or 6 doctors; sinusoidal, 2 or 3; Faradic, 2 or 3; diathermy, 10 or more; static, 1 or 2.

X-ray. Under the head of X-ray, we wish to call attention to the fact that it lists therapy only. There are four or five opportunities to secure service for fluoroscopic, and one for fluoroscopic and radiographic work combined, but only one or two that use the X-ray for therapy. We will note that there is some controversy as to the specific indications and contraindications for the so-called superficial X-ray therapy, nevertheless, there still remains a rather wide variety of cases than can receive benefit from this form of treatment. We hope to hear from one of this committee as to the excellent results obtained from X-ray therapy, with citations of cases to show results obtained.

Hospitals. The physical equipments of the hospitals of Ulster County are as follows:

The Kingston City Hospital: X-ray, ultra violet light, oven. The Benedictine Hospital; X-ray, ultra violet light, oven. Of course we expect to find items under the heading, thermal, as part of the routine practice of both institutions, as well as massage and manipulation.

Sahler Sanitarium: All items under thermal heading; daylight lamp, ultra violet light, infra red light, massage, manipulation, mechanotherapy, mechanical vibration. Electric: galvanic, sinusoidal, faradic, diathermy. Baths, other than ordinary types used in general practice,—shower, douche, cabinet, and a swimming pool. Occupational therapy.

County Tuberculosis Hospital: Occupational therapy.

There are three opportunities in Kingston, to secure properly given colonic irrigations under the supervision of a physician.

Practice by Physiotherapists—If information does not serve us falsely, and we have no reason to believe that it does, the physiotherapist is actually accepting patients who have not come through the regular and lawful channels of reference, the qualified physician, and is administering treatments to such patients. Also it happens that some cases, at least, that are referred by the physicians, get garbled discussions of their diagnoses, and, in some instances, the physiotherapist discovers new ailments that the doctors never dreamed of as existing. For example, a woman patient, on the verge of a nervous breakdown, was informed, when she appeared at the physiotherapist's for a colonic irrigation, that she had a tumor. One can imagine the state of mind, of this already nervous person, upon the receipt of such a new and startling diagnosis. It required

considerable talking on the part of the referring physician to convince the patient no tumor existed. It seems to be a fairly common practice on the part of the physiotherapist to inform the patients that they should come back for more treatments, this on their own initiative, and not by order of the referring physician,—at least the patients were not informed by the doctor that it was necessary to do so.

One chiropodist still continues to keep his sign, in evidence to the public, with the title Dr. before his name.

ULSTER COUNTY

Supplementary Report on Public Relations

A Public Relations survey of Ulster County was published in this Journal of January 15, 1930, page 105. A supplementary report was made by the Committee on October 8, 1930.

The Committee first gave an excellent report of the Conference of Chairmen of County Committees on Public Relations which was held in Albany, on September 28, 1930, and then reported on local affairs as follows:

Hospitals—The hospitals of Ulster County are not sufficiently recompensed for the services that they render the indigents of the county. It is suggested that there be further agitation in this regard and publicity, if necessary, and, if the County Society so desires, this matter can be taken up through the Committee on Public Relations. It is generally conceded that the "flat-rate" recompense to hospitals is unfair and unsatisfactory, and it is suggested that a "per diem" rate, which would more nearly recompense the hospitals for their services, be worked out. The Assistant Commissioner of Public Welfare pointed out that the doctors were not so definitely provided for. A Public Welfare official is charged with employment of a physician either in the hospital or in the home; but in order to hold it, there must be a written contract, and there apparently is no appeal over the decision of the Welfare official as to whether or not the doctor be employed. There is a provision whereby one emergency treatment may be given and then the Welfare official must be notified, but thereafter a written authorization for further treatments must be obtained. This whole subject of the new welfare law is a vast one and is being variously interpreted in different communities. It is suggested that the Ulster County Medical Society make an organized effort to apply this law in this community to the satisfaction of everybody concerned; and this will probably call for a conference of the Society or its representatives with the local Public Welfare Commissioners.

Medical Inspection of School Children—The chairman would like to touch briefly upon a public health activity that relates to the public and to the profession, and that is the working of the medical inspection of the public schools. The chairman was intimately connected with this work for the last two years as Medical Supervisor of the Schools in Kingston, and he found the work very unsatisfactory, not due to any opposition, but to the apathy and lack of interest and understanding on the parts of the profession, the school authorities and the public. The health department seems to be a stepchild's school system. The schools are charged by the State to carry out certain provisions of the law, but the school authorities seem to be content to carry out the bare requirements without inquiring or understanding fully the purpose of the law. This is reflected in the decision of the Board of Education of Kingston to dispense with the reading of the annual report of the Medical Department containing the results of the work of the year, and constructive recommendations for a future program, because it was "too long to read." The profession does not fully comprehend the medical inspection and yet the workings of this necessarily touch them individually and as a group. The attention of the doctors is so taken up with curative work that they are somewhat negligent of this aspect of preventive work,—that is the trend of modern medicine. Few physicians seriously undertook to make the physical examinations required every year of every school child, although the conducting of these examinations by the family physician is favored by the educational and medical authorities of the schools. If the family physician would do these examinations, it would mean a large revenue in his pocket, and it would mean that he would be lining himself up with the latest tendencies in medicine. Only a very small percentage of the school children were examined last year by the family physician. Eighty per cent of those in the public school were examined by the school doctor, and about twenty per cent were not examined at all, due to lack of time. Of the eighty per cent examined eighty-five per cent showed one or more correctible physical defects. The correction of these defects is the work of the family physician, and if he would take his work more seriously and cooperate better with the school doctor, he would be better off. Twenty per cent of the children examined showed defective nutrition. Probably in the majority of these instances the defect is called to the attention of the parent; in the minority of instances the parent probably consulted the family physician. It would be interesting to know how many of the family physicians were interested.

Over one thousand diseased tonsils were tabulated, and in the majority of the cases the parents were notified. No statistics are available but in a goodly number of cases this notification led to the removal of the tonsils. In three and one-tenth per cent of the children examined, defective or border-line defective hearing was discovered by the audiometer test.

Eighty cases of functional or organic disturbances of the heart were noted; and in this particular especially there should be greater cooperation between the school doctor and the family physician. The school doctor tried to be cautious in the handling of these cases and merely asked that a check-up should be made by the family physician. This check-up should be seriously done with the conservation of the sensibilities of all concerned.

Three hundred and eighty-one cases of orthopedic defects such as spinal curvatures, flat feet, etc., were tabulated. Probably the correction of very few, if any, of these cases will be undertaken by the local medical profession.

In over sixty per cent of the children examined defects of the teeth were found, and defective gums were noted. This work has been an example of what organized effort can accomplish. There was established through the efforts of the Kiwanis Club of Kingston a dental clinic for the treatment of indigent cases. This work has been accomplished to the satisfaction of all concerned. It is suggested that this organized work be extended to other defects, especially of the eye, ear, nose and throat. There is no doubt that economy and efficiency can be promoted by the organized treatment of indigents in clinics. There is a growing opinion that physicians should be recompensed for their work in behalf of the wards of the community.

Communicable Diseases—In the matter of the control of communicable diseases there are numerous misunderstandings between the family physician and the school doctor, and the health department, due to ignorance all around as to the duty and authority of each one concerned. These misunderstandings can be eradicated only by education.

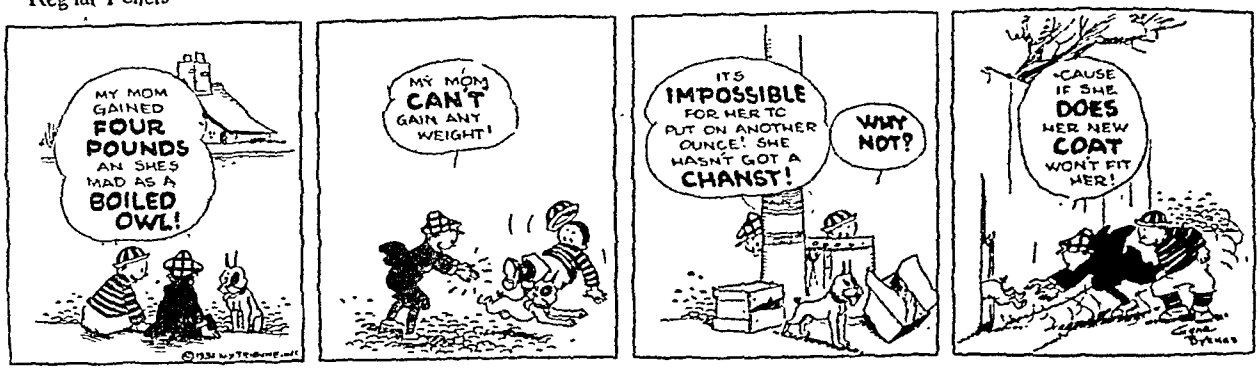
There is arising a monument to the concerted action of the Ulster County Medical Society in the new Tuberculosis Hospital, the cornerstone of which is to be laid in October, 1931. A new Tuberculosis Hospital will not be sufficient, but we shall have to formulate a tuberculosis program. This ought to be easier with the benefits which will come with a new hospital. It will involve the education of the public as to tuberculosis, and as to the proper use of the Tuberculosis Hospital. It will involve the education of the physicians in these matters, especially in the making of early diagnosis.

TRI-STATE CONFERENCE

The sixteenth session of the Tri-State Conference was held in the Chelsea Hotel, Atlantic City, on Saturday, December 6, 1930. There were present from New York Drs. W. H. Ross, J. N. Vander Veer, and J. S. Lawrence; from New Jersey, Drs. George N. J. Sommer and H. O. Reik; and from Pennsylvania, Drs. W. T. Sharpless, R. V. Patterson, W. F. Donaldson, F. C. Hammond, and A. C. Morgan.

The program was as follows:

1. A formal paper by Dr. Henry O. Reik, Editor of the *Journal of the Medical Society of New Jersey*, on the subject: "Automobiles more deadly than war. Can we control their death rate?" Dr. Reik developed the suggestion that a medical examination of all automobile drivers could be the contribution of physicians toward the prevention of accidents. The Conference adopted a resolution proposed by Dr. Reik recommending that the Medical Societies of New York, New Jersey and Pennsylvania devise a standard form of such an examination.



2. A paper, "Obligations of Professional Medical Service," by Dr. William H. Ross, President of the Medical Society of the State of New York. Dr. Ross suggested that organized medicine should develop plans by which practicing physicians could provide medical service to every individual of every social class at a reasonable cost to the patient or at public expense.

3. Informal after-luncheon discussion of the subject, "Should licensing of nurses be brought under control of State Boards of Medical Examiners?" The consensus of opinion of the speakers agreed with that frequently expressed by the special Committee on Nursing of the Medical Society of the State of New York.

The Conference voted to hold its next session in New York City.

THE DAILY PRESS

Reg'lar Fellers — Ounce of Prevention — By Gene Byrnes

From the New York Herald Tribune of January 12, 1931.

AGE OF POPULATION

Dr. Louis I. Dublin has an article in the Sunday Edition of the New York *Times* of January 4, in which he discusses the effects of the decline in the birth rate of the United States and other civilized countries. Commenting on the article, the *Times* of January 5 says:

"As the number of children to the family grows fewer, it is obvious that the percentage of young persons in the community will decline. In the United States in 1850 there were fifty-three persons under 20 years in every 100 of the population. In 1920 there were forty-one such persons, and in 1950 there will be only thirty-three. In England forty years ago the number of persons under the age of 15 was thirty-six out of every 100. In 1911 the number was thirty-two, and in 1921 it was twenty-nine. It may now be very near twenty-five. Forty years ago one English person out of three was a child. Now it is one out of four.

"Speculation finds a rich field in this prospect of an ageing world. Social students, for instance, are particularly concerned with the question of old-age dependency in a world with more old people beyond the working age and fewer children to support them. It is a fear which can be countered by the argument that, with fewer children to feed and educate, people may be able to save up more against their own old age. But more absorbing are questions on the mental and spiritual side. Will a world with fewer young people in it be less adventurous, more peaceful, more conservative, more interested in bread and butter and less in the fine arts? Largely it is guesswork. But one point of reference may be had. There is a nation which has been so far ahead of the others in losing its youth, so to speak, that it should be a fair indication of what is in store for the rest of us. That nation is France. Twenty years ago when in England and the United States the persons under 15 years of age were thirty-two in every 100, and in Germany thirty-four, in France they were only twenty-six. France is an 'elderly nation'; but affection between parents and children in France stands very high. That is one cheerful prognosis."

MOVIE OF A BRITON'S WILL

The medical application of the following news item from the New York *Times* of January 7 is that the audience assembled to hear the will read should include a physician to treat the emotional actions of those whose idiosyncrasies are exposed:

"The reading of the will of an elderly retired Birmingham manufacturer will be a novel and probably embarrassing experience for the beneficiaries and others whom he invited to attend it.

"The testator, according to *The Daily Express,* has had a talking motion picture made of himself reading the document. The order of the seats before the screen have been arranged so he can address each one individually.

"Not all the invited guests are beneficiaries. In an address from the screen he points out the faults and virtues of each. These criticisms will be delivered and the movie shown immediately after his cremation."

EMOTIONAL ADJUSTMENTS

The New York *Herald Tribune* has a brief daily feature called "More Truth Than Poetry," in which the author, James J. Montague, often illustrates a deep scientific truth in a few short verses. That of December 10 is on the subject of emotional adjustments, and reads as follows:

Young Tommy delighted in kicking his nurse
When he couldn't have pie for his lunch,
At the age of eleven his temper grew worse,
And he packed, for a child, a mean punch.
The village physician at last was called in,
But his verdict the family mistrusted,
For he said it was only original sin—
Not that Tommy was badly adjusted.

As the urchin grew up he would get into fights
With the much smaller children next door,
And stay out until 10 or 11 of nights,
While his parents were walking the floor,
When his mother was out for an afternoon call
He would put kerosene in the filter,
Which wasn't the fault of poor Tommy at all—
His adjustment was quite out of kilter.

At college he wore an expensive coon coat
And developed a liking for beer,
But never a theme or a thesis he wrote
And was flunked in his sophomore year.
He was sent the next term to a tutoring school,
But again he found out what a bust meant—
Which wasn't because the poor boy was a fool,
But because he was out of adjustment.

Now Tommy drives round in the family car,
Twenty jobs he has lately turned down,
But he knows the location of every bar
Within forty-five miles of the town.
His mother is plunged in the depths of despair
And his hard-working father is busted
And broken in spirit, but Tommy don't care,
For at last he is nicely adjusted.

DIET OF ANCIENT AMERICANS

An editorial in the New York *Herald Tribune* of October 7 calls attention to the fundamental differences in the native animals and plants of the New World as compared with those of the Old. It says:

"It is a curious fact that until Columbus's successor began carting back Indian foods to Europe, the two hemispheres lived on totally different diets. Tomato, potato, sweet potato, Indian corn, beans, pepper, Jerusalem artichoke, squash, pumpkin, peanut, even the tropical cassava, tapioca, avocado, pineapple and cacao, were unknown in the Old World; and the men of the New World had no knowledge of the rice, wheat, rye, cabbage, parsnips, carrots, peas, pears, plums, cherries, apples and other fruits which had for centuries made the Europeans fat. They did not even have the same domesticated animals, except for the Arctic dog. The turkey, the llama and the alpaca were unknown in Europe; the cow, horse, sheep and pig were strangers in America.

"As E. D. Merrill, the director of the New York Botanical Garden, remarks in pointing out the facts in the current issue of the Garden's 'Journal,' these are facts ruinous to the theory that the ancient civilizations of Peru, Central America and Mexico came, half mature, by ship from Europe, Egypt or from a sunken continent of Atlantis. 'What could have been the agriculture of the hypothetical Atlantis,' he asks, 'that transmitted to its supposed descendants in the two hemispheres not a single food plant and not a single domesticated food-producing animal in common?' A question which is a staggerer, indeed."

SIZE OF THE UNIVERSE

Man seems to stand about midway between the extremes of the very largest and the very smallest objects in the known Universe. Several calculations indicate this fact. The New York *Herald Tribune* of December 28 expresses this fact in a popular form in the following article:

"A scale in which each object in mass is about 1,000,000 times smaller than the object just above it is given by Professor John Q. Stuart, Princeton University astronomer. In the order of bigness these masses are:

1. The known material universe
2. A spiral nebula
3. A very large star
4. A good-sized planet
5. An ocean
6. A mountain peak
7. A forest
8. A man
9. A butterfly
10. A paramecium (single cell animal)
11. A bacterium
12. The largest organic molecules
13. A few score electrons
14. A quantum of ultra-violet light."

BOOK REVIEWS

NURSING IN EMERGENCIES. By JACOB K. BERMAN, A.B., M.D., F.A.C.S. 12mo of 160 pages, illustrated. St. Louis, The C. V. Mosby Company, 1929. Cloth, $2.25.

Dr. Berman's book gives a very complete description of the Emergencies, their symptoms and treatment. Possibly more stress should have been laid on the fact that all emergency treatment is merely a stopgap until the Doctor arrives. The text in places is too technical for laypeople and even the nurse might hesitate about administering Morphin and Strychnin without medical advice. The chapters are well arranged and on the whole the book ulfills its purpose. STANLEY B. THOMAS.

MINOR SURGERY. By ARTHUR E. HERTZLER, M.D., and VICTOR E. CHESKY, M.D. Second Edition. Octavo of 602 pages, illustrated. St. Louis, The C. V. Mosby Company, 1930. Cloth, $10.00.

This book includes a quite complete list of the pathological conditions that come under the heading of Minor Surgery.

As stated in the preface the methods of treatment are those of the Clinic in which the author works and can be accepted on that basis.

The chapters are arranged to cover the anatomical divisions of the body and the text is well illustrated.

For the worker in the dispensary this volume should have a distinct value. STANLEY B. THOMAS.

VENEREAL DISEASE: Its Prevention, Symptoms and Treatment. By HUGH WANSEY BAYLY, M.C. Fourth (American) Edition. Octavo of 242 pages, illustrated. Philadelphia, F. A. Davis Company, 1930. Cloth, $3.50.

The author has written a concise review of the important and far reaching subject of venereal diseases and has placed the essentials for the prevention, diagnosis and treatment of venereal diseases in a simple manner before the student and general practitioner. This is the fourth edition of this book and the author has brought it up to date in essential knowledge. He has added a few paragraphs dealing with the treatment of Paresis and Tabes by malarial inoculation as this treatment has now become an accepted method of therapeutics. It should be read by everyone who treats venereal diseases in his practice. PHILIP GOLDFADER.

THE MECHANISM OF THE HEART AND ITS ANOMALIES: Anatomical and Electrocardiographic Studies. By EMILE GÉRAUDEL. Translated, with an introduction by LOUIS FAUGÈRES BISHOP, M.A., M.D., and LOUIS FAUGÈRES BISHOP, JR., Ph.B., M.D. Octavo of 266 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1930. Cloth, $10.00.

The author has developed a new theory of the mechanism of the heart and of the method by which abnormal rhythms are produced. It differs radically from the prevailing conception and this volume is devoted to a presentation of his views. It is necessary to read the book in order to understand fully his thesis. Briefly, however, he believes that the heart is dominated by two independent rhythms, one for the auricle and one for the ventricle. He considers that there is an independent conduction system for the auricle—the atrionector and also one for the ventricle—the ventriculonector. He states that the changes in the mechanism of the heart which take place both in normal and pathological states are due to variations in the blood supply of these two systems. He has done much laborious work in order to try to prove his contention. He gives evidence of the various views both for and against his theory but it appears as if there is much against it that has not been fully expounded. The book is well produced and the illustrations are excellent. It ought to be studied only by those well versed in electrocardiography.

J. HAMILTON CRAWFORD.

MEDICAL GYMNASTICS AND MASSAGE IN GENERAL PRACTICE. By DOCTOR J. ARVEDSON. Translated and Edited by MINA L. DOBBIE, M.D., B.Ch. Third Edition. 12mo of 298 pages. Philadelphia, P. Blakiston's Son and Company, 1930. Cloth, $2.50.

The Orthopedist as well as the General Practitioner will find this translated edition, written by the leading authority of Swedish gymnastics and massage a great aid to their suggestions for treatment.

In a brief way he describes conditions affecting the skin, fractures, diseases of muscles and joints, deformities, diseases of the nervous system, circulation, respiratory, digestive and genitourinary organs.

His description is very elementary for the physician but should be a great guide for one engaged in instruction of the deformed. JOSEPH I. NEVINS.

THE PRE-SCHOOL CHILD AND HIS POSTURE: A Program of Corrective Exercises Through Games. By FRANK HOWARD RICHARDSON, A.B., M.D., and WINIFRED JOHNSON HEARN, B.S. Octavo of 220 pages, illustrated. New York and London, G. P. Putnam's Sons, 1930. Cloth, $2.50.

This little book sets forth clearly and in detail the underlying causes of the more common postural defects. Poliomyelitis, faulty furniture as well as the radical change in the social economic system of our civilization, all of these are accounted for as the cause of postural defects.

Corrective exercises as recommended in this treatise are in the form of games. A far more desirable method to the method of old, namely that of command. Photographic illustrations add color as well as simplicity to the subject matter.

The authors have shown their thorough knowledge of child psychology as well as their thorough familiarity with the management of postural defects in children.

This booklet should prove an aid to the teacher of the kindergarten class especially. HARRY APFEL.

HYGIENE FOR NURSES. By JOHN GUY, M.D., and G. J. I. LINKLATER, O.B.E., M.D. 12 mo of 212 pages. New York, William Wood and Company, 1930. Cloth, $1.75.

The data presented in this book should be of value not only to nurses but to others interested in topics of health. In fact, a good deal of the information has no bearing on the bedside or hospital duties of a nurse.

For example, in the chapter on diet, two uncommon articles are strongly recommended on account of their rich vitamin content—oysters and dandelion leaves. The virtues of different types of clothing are interpreted in terms of their physical properties. And if the reader be interested in matters of prophylaxis he may find in this splendid handbook a discussion of the different types of water supplies in relation to organic pollution; the importance of standard humidity in conjunction with an optimum room temperature; types of heating devices, and other topics which we often overlook in aiming to seek the causes of respiratory disorders.

EMANUEL KRIMSKY.

A System of Bacteriology in Relation to Medicine. [By Various Authors] (Prepared under the direction of the Medical Research Council) Volume I Octavo of 374 pages illustrated London His Majesty's Stationery Office, 1930 Cloth (Set of 9 volumes, £8 8 0)

Vol I of the System of Bacteriology published by the Medical Research Council is devoted to the history of bacteriology and to consideration of the general characteristics of bacteria

The historical section is most interesting The author has not only studied the original writings of all contributors to the literature of bacteriology from Leeuwenhoek down but has delved into the early Greek and Roman writers for their ideas on disease In the space of 70 pages he gives an admirable account of the theories and methods of dozens of men with reproductions of illustrations in the original papers This story of the development of bacteriology should interest all physicians and many laymen

The remaining chapters deal with bacterial morphology physics, growth disinfection, metabolism and respiration classification and variation The specialist will find here a wealth of detail summarizing all that is known on these subjects

E B Smith

Physical Diagnosis By Richard C Cabot M D Tenth Edition (Revised and Enlarged) Octavo of 529 pages, illustrated New York, William Wood & Company, 1930 Cloth, $5 00

This standard work needs no introduction so long has it been the practitioner's handbook This the tenth edition presents laboratory advances of special value and discusses thoroughly the diagnosis of coronary disease, pulmonary carcinoma, cardiac asthma toxic hepatitis and encephalitis lethargica, in addition to the more familiar topics which this work has, in the past presented so clearly and concisely Electrocardiography of course receives full consideration The student the practitioner and those engaged in diagnostic services in many fields will find this book, as always, wholly dependable

A C J

Applied Bacteriology for Nurses By Charles F Bolduan M D Sixth Edition revised and enlarged Octavo of 251 pages illustrated Philadelphia and London W B Saunders Company 1930 Cloth $2 00

This book has won recognition among training schools for nurses It is an excellent text book because it presents the subject in a manner applicable for nurses In this new (sixth) edition sections and discussions have been added on the following subjects Undulant Fever, Tularemia Active Immunization against Diphtheria by means of Toxoid the Semple Method of Immunization against Rabies and the Immunization of Infants against Tuberculosis by the Calmette Bacillary Vaccine The book is highly recommended for nurses

Silik H Polayes

Slit Lamp Microscopy of the Living Eye. By Dr F E. Koby Translated by Charles Goulden, O B E and Clara Lomas Harris M B Second Edition Octavo of 360 pages illustrated Philadelphia P Blakiston's Son & Company, 1930 Cloth $4 50

The second edition of this 'Summary' is as refreshing as was the original Though the first edition was the first text on the subject in English, the second adds so many new sections as to reawaken one's ambition to master slit-lamp microscopy

To this book belongs much of the credit of establishing biomicroscopy as a necessary and useful clinical study

The first parts of the book discuss the instruments which have become popular in Germany France England and the United States Normal studies and characteristics are then taken up the final two-thirds of the book being taken up by study of pathological entities One would think the work a little heavy for the beginner and likely to discourage him It is however the only text to which one can turn for a detailed description or explanation of almost any aspect of the subject It suffers less than the original edition from those defects which are common to all translated works It is altogether a very worthwhile contribution J N Evans

Physiological Principles in Treatment By W Langdon Brown, M A M D with the collaboration of R Hilton M A M B Sixth Edition 12mo of 464 pages New York William Wood & Company, 1930 Cloth, $3 75

This edition appears twenty one years after the first and many sections are considerably changed The chapter on Nephritis presents the modern conception of many features of this disease and is especially good in its consideration of diet This section may be read with benefit, especially by those physicians who still prescribe markedly undernutrition diets for patients suffering from nephritis without nitrogen retention

The different types of glycosuria are discussed at some length and many important facts are concisely presented here The scanty ladder diet' of Graham is still given in detail but since the advent of insulin, this, with other diets of its type does not seem to be needed

This is an interesting small book which presents much information in a convenient form

W E McCollom

Allergic Diseases, Their Diagnosis and Treatment By Ray M Balyeat M A M D, F A C P Octavo of 395 pages illustrated Philadelphia, F A Davis Company, 1930 Cloth $5 00

The title of Dr Balyeat's book is a little misleading to medical readers as one might expect a treatise on the Diagnosis and Treatment of Allergic Diseases However, the book in reality is a manual for the laity upon the subject of Allergy It is very well done from that standpoint and should be interesting to patients suffering from Hay fever, Asthma etc.

It is apparently designed to help these patients cooperate with their physicians in the cure of their troubles It ought to serve to fulfill this purpose admirably but should not be considered a reference book upon the subject of Allergy

E P Maynard, Jr

Some Aspects of the Cancer Problem By W Blair Bell B S M D Lond F R C S Eng, Hon F A C S Quarto of 543 pages illustrated New York William Wood & Company 1930 Cloth, $20 00

Dr Bell and his associates have prepared a volume of over 500 pages well illustrated that deals essentially with the effect of Lead on cancer In a scientific publication of this kind there is naturally a mass of 'incidental spade work, chemical mathematical and clinical, through it all the reader will appreciate the effort at coordination and sequence

The editor creates a working hypothesis by the utilization of scientific data that neoplastic deviation from normal differentiated somatic growth might be a reversionary process of somatic differentiated cells back to their embryonic state (chorionic epithelium) due to metabolic disturbances (starvation) To substantiate this theory there is offered histological physicochemical and physiological evidence of similarity between the chorionic epithelium and neoplastic tissue The similarity of specific action of Lead on cancer cells and chorionic villae is portrayed

The general principles of chemotherapy in malignant disease are then set forth with a complete review of the various preparations of Lead The toxic symptoms of Lead and how to avoid them, the technique of Lead therapy alone and in conjunction with surgery x ray and radium are fully discussed

OUR NEIGHBORS

POST-GRADUATE COURSES IN IOWA

The Journal of the Iowa State Medical Society for December describes the following plan for post-graduate work in Iowa:

"When this issue of the Journal reaches you, the first real project of the Speakers' Bureau will be in full swing. During the first week in December, extension courses were opened in five places, making it possible for physicians in neighboring vicinities to do post-graduate work. The cooperation of the State University of Iowa with the State Medical Society gives this unusual opportunity to Iowa physicians. The University outlined a number of courses which faculty members of the College of Medicine were willing to give, if a sufficient enrollment would be provided. The five towns which evidenced the most interest at this time were Waverly, Fort Dodge, Carroll, Des Moines and Oskaloosa. The courses chosen this year were the lectures on Obstetrics by Dr. E. D. Plass, head of the Department of Obstetrics, and a course on Cardio-vascular diseases under Dr. Fred Smith, head of the Department of Internal Medicine.

"The enthusiasm with which the physicians have registered for these courses is merely another indication of the progressive spirit of the medical profession in Iowa; Doctors are driving many miles to take advantage of this opportunity to advance themselves professionally. The members of the Bremer County Medical Society enrolled one hundred per cent to support this enterprise. In order to reach the greatest number at least expense, a route was planned to include a circuit of five centers. These courses began on December 1 at Waverly and the other towns followed on successive days. The same schedule is followed for a period of ten weeks. Two hours each week are devoted to each course, making a total of forty hours of intensive study. Upon the completion of the courses, examinations may be taken and certificates issued by the University to those qualifying.

"In order to get these courses started at once, the Bureau made arrangements for only one circuit. The committee realizes, however, that many other Iowa physicians are eager to have this privilege of keeping abreast of the times, and they will therefore be glad to schedule a circuit of extension work for other sections of the state that ask for such service."

WELFARE COMMITTEE OF NEW JERSEY

The January number of the Journal of the Medical Society of New Jersey contains the minutes of the meetings of the Welfare Committee held on November 9 and December 14, 1930. This committee has thirty-five members, and performs several functions, among them being legislation and public relations.

The first business noted was a discussion of a plan proposed by a collection agency for the collections of doctors' bills. The experiences reported by members of the Committee were not favorable to the general plan of collecting bills, and the proposition was rejected.

The question of the employment of unlicensed medical practitioners by State institutions was discussed, but the decision was that further light would be required.

"The Executive Secretary presented a document prepared by Dr. Morrison in explanation of the State Society work and the manner in which the Society's funds are expended, and recommended that this be printed in the form of booklet previously used with reference to auxiliary matters and in explanation of cultism, and that these booklets be distributed for the edification of members of the State Society and for the use of officers of county societies in collecting dues and in procuring new members.

"A motion was duly passed approving the publication and distribution as recommended."

The committee held a lengthy discussion on the proposal that the several examining and licensing boards—a dozen or so in number—shall be placed under the control of either the State Commissioner of Education, or, as in New York State, the State Regents. Dr. Reik, the Executive Secretary, reported:

"We are in grave danger of being swept into a false position through the influence of mob psychology. The appearance of these legislative bills, indeed the preceding newspaper stories about what the Abell report *would* contain, planted in our minds *a fear* that something ter-

(Continued on page 174—adv. xii)

DETOXIFICATION IN THE BOWEL

THE principles of detoxification with Soricin (purified sodium ricinoleate), first enunciated by Larson, has been amply confirmed in dental practice.

The action of Soricin as a detoxifying agent is based upon its ability to render most pathogenic organisms non-pathogenic, and to detoxify their toxins. This prevents the absorption of toxins from such foci of infection as can be reached and the consequent development of secondary infections.

Following the confirmation of Larson's work by Cesari, Cotoni and others at the Pasteur Institute, and the extension of that work to the field of immunology, Morris, Dorst and others have turned to the investigation of the possible value of Soricin as a detoxifying agent in the intestinal tract.

During the past two years clinical studies show that Soricin Capsules, given by mouth, usually afford prompt relief in mucous colitis and other diseases of the intestinal tract associated with bacterial hypersensitivity.

Quoting from a recent article by these investigators, which appeared in the *American Journal of Medical Sciences*, November, 1930, No. 5, Vol. clxxx, page 650, the authors state in their conclusions: "Sodium ricinoleate detoxifies many organisms in the enteric flora in vitro, as demonstrated by the disappearance of skin reactions upon the injections of strains which, before detoxification, have given marked reactions. There is worthy evidence to suggest that sodium ricinoleate, administered by mouth, exerts a detoxifying action on the enteric flora in vivo."

If you are interested in this work, we will be glad to send you the available data, together with a supply of Soricin Capsules for test in your practice. THE WM. S. MERRELL COMPANY, CINCINNATI, OHIO.

CROOKES' COLLOSOLS

℞ **COLLOSOL MANGANESE**
For boils, acne, and all suppurative affections

℞ **COLLOSOL ARGENTUM**
Stainless, non-irritating colloidal silver, for eye, ear, nose, throat and genito-urinary affections.

Full information and samples for clinical trial will be sent on application to

rible was going to happen. That fear has grown to the point where we are in danger of acting unreasonably. I have heard much talk about these bills but most of it has been irrelevant, based upon fear rather than study of the bills, and some of it has *entirely misrepresented* the apparent intent and the *actual wording* of the bill. I have heard it argued that these bills propose abolition of the Boards of Examiners, substitution of examinations by persons incapable of conducting appropriate examinations, the employment of an immense force of adjunct employees to carry on the work, and the application of funds properly received by the Boards to State work other than that heretofore carried on by the Boards. There is not a word in either of the laws to justify any of those criticisms."

The committee finally voted to oppose the bill.

The committee also considered the form of blanks for reporting on the defects of crippled children and quoted the executive secretary as follows:

"The present proposition is to utilize the customary Health Department blanks for births and still-births, adding to such books of blanks, in the front portion, several blank forms to be used when necessary. On the regular blanks would be printed a line directing attention to the necessity for filling the special blanks whenever there exist deformities that should be reported. The special bank provides for recording the name, address, date of birth, type of deformity, whether under treatment or referred to other physicians or surgeons, and the signature of the attending physician. The Commission and the Health Department would like to have immediate consideration of this matter so that if approved the certificates can be prepared for new blanks about to be ordered by the Department."

The preparation of the forms was approved.

The committee voted to investigate rumors that certain hospitals were making contracts with industrial companies for the care of injured workmen.

The committee also considered the advisability of making agreements between doctors and the carriers of workmen's compensation insurance similar to those in New York State. A sub-committee was appointed to investigate the subject.

WHITE HOUSE CHILD CONFERENCE, A MASSACHUSETTS OPINION

The best summary of the White House Child Conference held in the latter part of the year 1930, is the following description in the *New England Journal of Medicine* of December 18, 1930:

(*Continued from page 174—xii*)

"President Roosevelt in 1909 ordered a White House Conference on the Care of Dependent Children. From this resulted the Children's Bureau, organized in President Taft's administration and made part of the Department of Labor when that was created in 1913. In 1919 President Wilson called a White House Conference on Minimum Standards of Child Welfare. The study and insurance of the health and happiness of United States children being traditionally, according to *Time,* a presidential concern, President Hoover therefore called last year a Conference on Child Health and Protection. Dr. Ray Lyman Wilbur is chairman of this committee and Harry Everett Barnard, of Indianapolis, its Director.

"Last month the Conference—over 3,000 individuals—met in Washington to report the result of its investigations and to make recommendations. Of 45,000,000 children in the United States, more than 10,000,000 were found to be handicapped, as follows:

Improperly nourished	6,000,000
Defective speech	1,000,000
Weak or damaged hearts	1,000,000
Behavior problems	675,000
Mentally retarded	450,000
Tuberculous	382,000
Impaired hearing	342,000
Totally deaf	18,000
Crippled	300,000
Partially blind	50,000
Wholly blind	14,000
Delinquent	200,000
Dependent	500,000

"And yet, as President Hoover said in his address, 'That we be not discouraged let us bear in mind that there are 35,000,000 reasonably normal, cheerful human electrons radiating joy and mischief and hope and faith. From what we know of foreign countries, I am convinced that we have a larger proportion of happy, normal children than any other country in the world And also, on the bright side, we have 1,500,000 specially gifted children. There lies the future leadership of the nation if we devote ourselves to their guidance.

"Nineteen recommendations were made by the conference, eighteen constituting a bill of rights, the nineteenth recommending the organization of districts, counties and communities for child health, education and welfare, with: (1) trained full-time public health officials with public health nurses, sanitary inspectors and laboratory workers; (2) available hospital beds; (3) full-time public welfare services for the relief and aid of children in special need from poverty or misfortune, for the protection of children from abuse.

(*Continued on page 179—xvii*)

Before the Operation and After

In preparation for the operation  one tablespoonful of Agarol on retiring  in place of the usual castor oil, will insure against gastric upset.  Again, a few days later  when the patient begins to take nourishment  Agarol in half doses  is the logical eliminant because it stimulates peristalsis  gently without griping or pain.

AGAROL is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Agarol is palatable without artificial flavoring and easy to take. The usual dose in chronic constipation is a tablespoonful, reduced as improvement takes place.

A supply gladly sent for trial.

AGAROL *for Constipation*

WILLIAM R. WARNER & COMPANY, Inc. 113 West 18th Street, New York City

New York Post-Graduate Medical School and Hospital

offers courses in

ROENTGENOLOGY

A basic course of six weeks in the principles and practice of roentgenology is followed by an advanced course of six weeks in plate interpretation, fluoroscopy, and therapy. Admission to the advanced course is granted to those who have completed the basic course, or who have had at least 5 years' experience in roentgenology. ¶ Further instruction in roentgenology may be individually arranged for on completion of the three months' work. ¶ Under the direction of Dr. William H. Meyer. ¶ Licensed physicians in good standing are admitted to these courses. ¶ The next basic course begins April 6; the next advanced course begins May 18.

NURSES' EXAMINATIONS IN PENNSYLVANIA

The Pennsylvania Medical Journal of January has an editorial comment on the severity of the examinations given to nurses, and says:

"We reproduce here an article that appeared in the Clearfield County (Pa.) Medical Society *Bulletin* for December, 1930.

"Why our Daughter did not complete her Nursing Course

"There has been a great deal of discussion in current medical journals as to what branches of the medical science and how much of it should be taught in the training schools for nurses. It is generally believed that too much time is spent in classrooms and not enough in the hospital wards. Below is a copy of an anatomy examination given to a first year class of nurses to determine whether they were qualified to continue their training course. It is not known how many of them passed the examination, but if they did, and the other subjects taught them were as difficult, they should have been given a license to practice medicine.

"1. Name the systems of the body. Classify tissues and give an example of each class.

"2. Describe the spinal column.

"3. Classify muscles; give one example of each class. Name two principal muscles of the arm and state their function.

"4. Describe the lungs. What takes place as a result of pulmonary circulation?

"5. List the functions of the blood. Compare the structures of an artery, vein, capillary; what blood does the portal vein carry to the liver?

"6 Discuss in detail the thoracic duct.

"7. Name the enzymes of the pancreatic juice and give the function of each one.

"8. Name the principal nerve center of the body and the parts that compose it.

"9. Name the excretory organs of the body and give the principal waste products excreted by each.

"10. Describe one serous cavity of the body.

"11. Define the following: Metabolism, lymph, omentum, foramen, fossa, process, condyloid, sagittal.

"12. Describe and locate the temporal bone.

"13. List the ductless glands and state the supposed function of each.

"14. Name the organs contained in the female pelvis and state the function of each. Describe fully one of these.

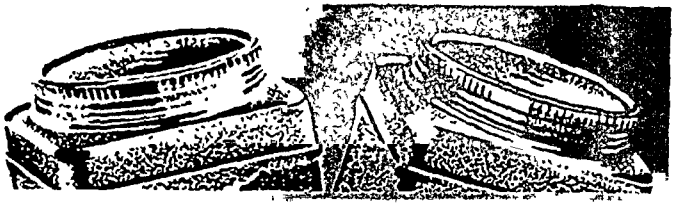
"As stated, these constitute questions given in one subject only, anatomy, but will afford an idea of the type given in the remaining subjects. How many of our medical readers can satisfactorily answer all the questions herewith given, which, please remember, were for first year pupil nurses?

"Who is to blame for the condition of affairs herewith set forth? The medical profession should admit its guilt. It is responsible for not having controlled the affairs of nurses' training schools, in all respects, and should have been on guard in the legislative halls. How long is this condition of affairs to continue before organized medicine will lend its cooperation to aid in its correction?"

The same condition of affairs prevails in New York State. A similar set of questions given from 1922 to 1925 was published in the NEW YORK STATE JOURNAL OF MEDICINE of February 15, page 168.

FULL TIME HEALTH OFFICERS IN ILLINOIS

The Illinois Legislature is considering a bill permitting counties to establish health departments on petition, and providing that the full time health officer shall receive "an adequate living salary, but in no case to exceed $5,000 per annum."



The Journal of the Indiana State Medical Association for January devotes several pages to the bill, both for and against it, and says that the House of Delegates voted in opposition to it. A two-page editorial gives the following arguments:

"At the present time it is impossible to secure enough medical men who have been educated and trained in public health work to fill positions as all-time health officers. An all-time health officer not only should be qualified and trained for the position but he should be paid an adequate salary. Inasmuch as the people at this particular time are crying for economy, it is doubtful if such an increase in public expense as required to pay decent salaries to all-time health officers would be considered. At present the positions made possible by the bill no doubt would be filled by derelicts and incompetents who have made more or less of a failure of the practice of medicine.

"The expense will be burdensome on some communities, and already there is a cry for more economy in expenditure of public money.

"It is admitted that the larger cities of the

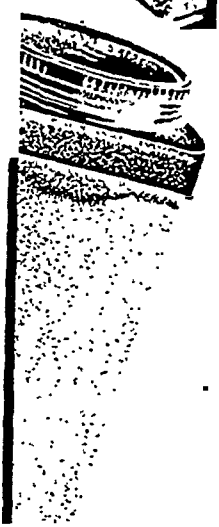
Alkalinization in Common Colds

BiSoDoL
An unusually palatable form of alkaline medication

Gastric Hyperacidity
"Sour" Stomach
Acid Eructations
"Heartburn"
Acid Dyspepsia
Nervous Dyspepsia
Gastric Pain
Acid Urine
Acidosis
Vomiting in Pregnancy
Sea Sickness
After Anesthesia



So many authorities stress the value of alkalinizing the patient in the prophylaxis and treatment of colds that this procedure is becoming almost routine. Alkalis are stated to favor recovery and prevent complications by combating acidosis.

BiSoDoL affords a safe, effective and palatable antacid for this purpose. At the beginning of a cold, one teaspoonful in water may be taken every two hours until the symptoms are relieved.

BiSoDoL affords "Quick Relief" in gastric hyperacidity and the common dyspeptic symptoms. Also indicated for its systemic value in helping to control cyclic vomiting, vomiting of pregnancy, post-anesthetic nausea, after alcoholic indulgence, etc.

BiSoDoL is ethically presented to the physician.

Question:

Calcium Assimilation?

Answer:

Cases in Point—

Mr. C. C. S——, Railroad express messenger. Came here, was on the verge of T. B., underweight, cough, night sweat and very anemic; loss of appetite and highly nervous. Put him on Olajen for thirty days. He has gained fourteen pounds and never felt better in his life. I know that Olajen did the work. Patient's weight, November 2, 120 pounds; December 9, 134 pounds.

December, 1930. ————, M.D.

Miss Ruth R——, Age 11, Weight 68 pounds. Examined by me October 12th and found to be highly Neurasthenic, Anemic, Enlarged Thyroid and Gastro Intestinal Catarrh. Was put on a plain diet and the daily use of Olajen three times a day after eating. Examined again on November 30th and patient showed marked change and improvement in every way. Was 78 pounds, fine color and vigorous. The parents were highly amazed and pleased at the change and rightly gave Olajen credit for results. I obtain similar results in all my cases where Olajen is used.

December, 1930. ————, M.D.

Miss M. C. C——, Age 27, Weight 104, Height 5:1. First office call on November 4th, 1930. Patient was Neurotic, Anemic and underweight, Jaundiced, Gastro Intestinal Catarrh and Bowels sluggish; felt tired and worn out. Was placed on Olajen November 4th, four times a day after eating and placed on diet of simple nature. She has improved steadily and is highly pleased. Bowels are O. K. Neurotic condition absent, sleeps and eats well and now weighs 115 pounds. This is another history of the several satisfactory cases I have treated with Olajen.

December, 1930. ————, M.D.

Composition—Olajen contains per 8 oz.—calcium lactate, 12 gr.; iron phosphate, 12 gr.; sodium phosphate, 12 gr.; potassium bi-tartrate, 12 gr.; lecithin, 4½ gr.; in a colloidal nutritive base with an agreeable chocolate mint flavor.

MAY WE SEND YOU LITERATURE?

Olajen, Inc.

451 West 30th Street

New York City

(*Continued from page* 180—*adv. xviii*)

state can afford and should have all-time health officers. However, even they will have great difficulty in securing medical men adequately equipped for the position, no matter what salary is paid. The difficulties increase when you get away from the city. The all-time health officer bill makes it possible for the development of a machine that may be ruthless in its work of perpetuating itself and establishing an intolerable domination. There also is a possibility of autocratic domination by the secretary of the State Board of Health, who, according to the terms of the bill, in a sense is a dictator.

"In the majority of the counties of the state the health officers have been fairly representative men, and, as was stated before the House of Delegates at the Fort Wayne session, we are better off to have the part-time services of a good man than the all-time services of a poor man.

"The full-time health officer project, no matter how much you camouflage it, is a stepping stone to state medicine, and there is ample proof ta indicate that some of the most ardent advocates of the full-time health officer enterprise are openly or secretly in favor of and even working for the adoption of state medicine. It is a very natural thing for them to feel that way, for, if state medicine does come, the full-time health officer will be on the top wave and he will be the first one to profit.

"It is impossible at the present time to secure well-educated medical men who have had adequate special training in public health work to fill all-time positions, even in our cities; and that fact alone is one of the principal reasons for objection to the project under discussion, for we do not believe in creating positions without having educated and trained men to fill them."

NEW MEDICAL CENTER IN LOUISIANA

The *New Orleans Medical and Surgical Journal* for January has the following outline of a new method of clinical teaching of medical students and new headquarters for the Louisiana State Medical Society:

"The exercises on the night of December tenth, when the New Hutchinson Memorial Building was formally opened, marked an epochal event in the Medical School of Tulane University, and one which should be of importance to the medical profession of New Orleans and Louisiana. The new building, made possible by a contribution of $1,250,000 from the General Educational Board of the Rockefeller Foundation, will be utilized for the carrying out in every way the purposes of the bequest of the late Mr. Joseph Hutchin-

(*Continued on page* 183—*adv. xxi*)

(Continued from page 182—adv. xx)

son. It will be devoted to the care of the ambulatory sick and the injured, and at the same time will be utilized for the purpose of instruction of medical students in a manner which is both unusual and without precedent. Each student will be given his own office, wherein the working arrangements will resemble closely those of private practice. Here he will examine and treat patients assigned to him under the supervision of an instructor. There are 105 such offices in the new building under the different divisions of the medical school. Each of the offices is equipped with small dressing room, examining table, desk, laboratory table with equipment, a centrifuge, and a wash-stand. In addition to this novel pedagogic arrangement there are other laboratories where diagnostic and therapeutic procedures more complicated than routine office procedures may be carried out. There are also laboratories for the staff, teaching rooms, conference rooms, an auditorium and other facilities which will go to make a most complete medical school.

"On the first floor of the building, quarters have been assigned to the Louisiana State Medical Society. A large, bright, sunny and cheerful secretaries' room is part of the suite which contains as well the office of the Secretary-Treasurer and the Editor of the *New Orleans Medical and Surgical Journal*. The Secretary of the Orleans Parish Medical Society also has an office in this same suite, and adjoining it is a large board room furnished magnificently by the Orleans Parish Medical Society. The Library of the Orleans Parish Medical Society is just above the offices of the State and Parish Societies which are connected with it by a private stairway and small private elevator. The library of the Orleans Parish Medical Society and the Tulane Medical School Library, while housed in the same stack room, are filed separately. They are under the care of the same library force so that duplications are avoided in both the book files and current medical journals. In this way there is splendid opportunity for enlarging the Library, which already is the largest in the South and which has possibilities of being made one of the largest in the United States.

"The close relationship of this new Hutchinson Memorial Building to the Charity Hospital, the propinquity of the Hotel Dieu and the Eye, Ear, Nose and Throat Hospital make for a potential hospital center in which many of the members of the Society already carry on the bulk of their medico-charitable activities as well as some of their practice in those hospitals accepting private patients."

Lowers Blood Pressure and KEEPS it down

Pulvoids Natrico effects a reduction of blood pressure that is not a matter of minutes or hours, but of days.

Experiments have proved that lowering of tension produced by the drugs classified as vasodilators is of short duration. Effect of amyl nitrite lasts 7 minutes, nitroglycerin 30 minutes, sodium nitrite 2 hours.

But Pulvoids Natrico, a synergistic combination of approved vasodilators (sodium nitrite, potassium nitrate and nitroglycerin) in combination with Crataegus Oxyacantha, not only lowers blood pressure but keeps it down safely and surely, pending determination and treatment of the cause.

Try Pulvoids Natrico for yourself and check its results against the sphygmomanometer.

"We condemn those who commit and almost equally those who defend and uphold these old-time practices. These things we know are perpetuated by a certain type of persons, of very different order to the generally beloved and welcome doctor in ordinary medical practice—and it is to this body of doctors that we are submitting this letter, and from whom we are certain we will receive a courteous response."

The questions submitted to the doctors are as follows:

"1. In the interests of the great commercial serum-producting companies, to provide material for scientific curiosity, and as demonstrations before students, living and conscious animals are put to much suffering, mutilation and death, in research laboratories. In your opinion, is this both justifiable and ethical?

"2. Do you approve of methods born out of vivisection?

"3. Do you believe in and make use of sera?

"4. Do you approve of the Schick test?

"5. Would you administer serum to your own children?

"6. Do all sera contain the virulent germs of the very disease they are intended to prevent and cure?

"7. Do you think past results justify the continued use of the so-called preventive sera?

"8. Do you believe in the efficacy of antitoxin?

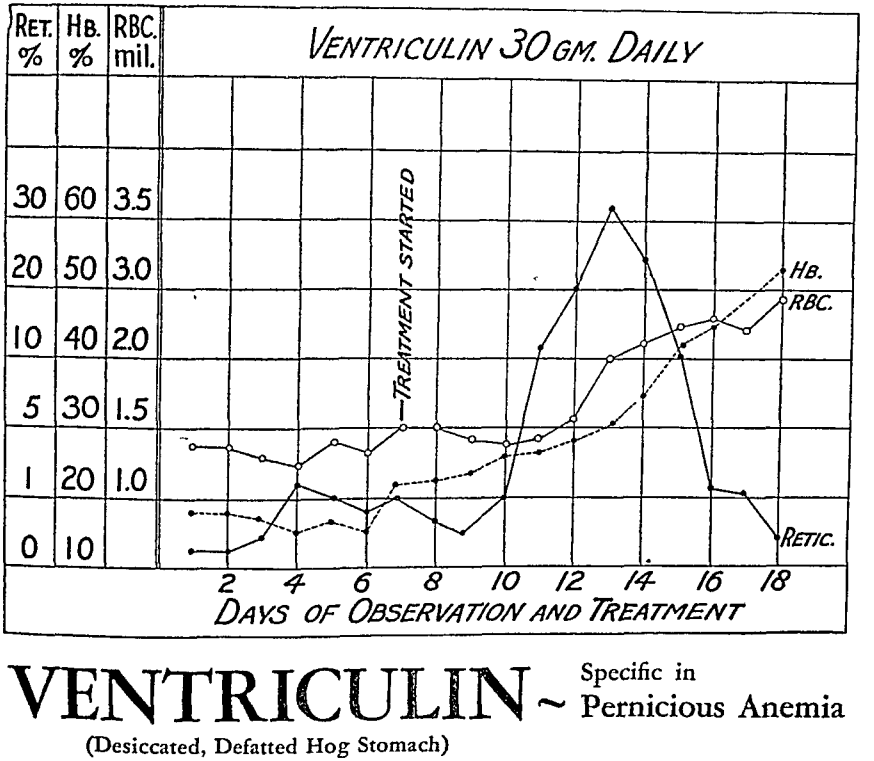
"9. Will you guarantee that the use of serum antitoxin, or any other similar preventive method, or cure, will have no harmful effects?

"10. Is it not a fact that there is a wide difference of opinion among medical men as to the benefits of serum therapy?

"11. Do you believe in the efficacy of vaccination as a preventive of smallpox?

"12. Will you guarantee that vaccination will have no harmful after effects?

"13. Will you guarantee that vaccination will prevent smallpox?



"14. In your opinion what has been the chief factor in the decline of smallpox—vaccination or improved sanitation?"

SOCIAL TRENDS IN MEDICINE IN WISCONSIN

Dr. C. A. Harper, writing the "President's Page" of the *Wisconsin Medical Journal* for January, discusses social trends in medicine as follows:

"The flocking of physicians to the larger cities, specialization and the building of hospitals in the larger communities, are no small factors in bringing about existing conditions, indicating that some form of social medicine must be developed in order to meet the wants of the general populace.

VENTRICULIN ~ Specific in Pernicious Anemia

(Desiccated, Defatted Hog Stomach)

Accepted for N. N. R. by the Council on Pharmacy and Chemistry of the American Medical Association.

Summary of findings in typical case of pernicious anemia treated with Ventriculin and illustrated in above chart.

DIAGNOSIS. Pernicious anemia.

INITIAL BLOOD COUNT: Red blood cells 1.5 million per cu. mm.; Hemoglobin (Newcomer) 21 per cent; Reticulocytes 1.0 per cent.

TREATMENT. Ventriculin 30 Gm. daily.

PHASE OF REMISSION. *On sixth day of treatment:* RBC 2.0 million; Hemoglobin (Newcomer) 30 per cent; Reticulocytes 32.0 per cent (calculated rise for 1.5 million red blood cells at beginning of treatment = 22.3 per cent, exceeding expected rise by 9.7 per cent).

PROGRESS REPORT. On the twelfth day after Ventriculin was begun the following blood count was recorded: RBC 2.9 million; Hemoglobin 52 per cent; Reticulocytes 0.4 per cent. (Expected weekly increase = 500,000 red blood cells per cu. mm. Actual increase in this patient = 700,000 red blood cells per cu. mm.).

A Booklet on Pernicious Anemia will be sent you promptly on request.

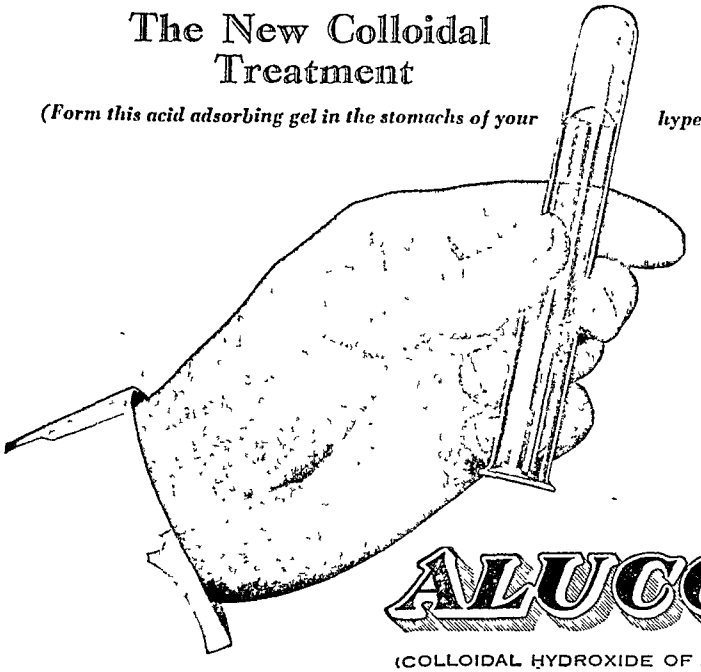
"Industries, life insurance companies, and many communities are seriously discussing this phase of medicine. Sixty-two per cent of the hospital beds are now directly or indirectly under federal, state, county, or municipal control. It is estimated in Allon Peebles 'Survey of Statistical Data and Medical Facilities in the United States,' published in November, 1929, 'that there are about 1,500,000 persons whose services are utilized by the inhabitants of the country in connection with the curing of illness, including physicians, dentists, osteopaths, chiropractors, christian scientists, etc.' It is estimated that there are at least 200 foundations, none of which have less than $10,000,000 at their command, that are engaging in the field of health and general welfare. It is readily seen that there are tremendous forces outside of the ethical pale of the practice of medicine that are working in the field of general welfare.

"These facts strongly emphasize a popular demand for certain changes that will comply, more or less, with the wishes of the general public. Is it wise for the medical profession to remain indifferent to the problem while these agencies are developing certain lines of activity; or would it not be far better for the medical profession to appreciate the evolution that is now taking place, and become a prominent factor in guiding these various lines of procedure.

"At the least, it presents a problem of much study and serious thought, and the object of this article is not to champion state medicine or social medicine, but to champion scientific medicine in all its branches. It is to emphasize its importance to the welfare of the people and bring to them an appreciation of the fact that only a well-trained, properly qualified medical man can give that service which is essential for the welfare of the public as a whole."

PUBLIC RELATIONS IN INDIANA

The December issue of the Journal of the Indiana State Medical Association has an account of the meeting of the Allen County Medical Society, which seems to bear the technical name of Fort Wayne Medical Society of October 7, when the relation of the Society to the Community Chest was discussed, as follows:



"Dr. Schafer made a brief report to the effect that the Medical Society as a group was giving to the Community Chest clients no less than $20,000 in actual service a year. He asked to be instructed concerning what the society wished to be done in the way of es-

ACID STOMACH

The New Colloidal Treatment

(Form this acid adsorbing gel in the stomachs of your hyperacid cases)

ALUCOL

(COLLOIDAL HYDROXIDE OF ALUMINUM)

Doctor, have you tried the newer and better colloidal way of treating acid stomach? Physicians who have found certain decided objections to the use of alkaline antacids are showing a preference for this new method. It involves the use of a non-toxic colloidal type of aluminum hydroxide, known as Alucol.

In the Sixteenth Session of the French Congress of Medicine, Professor Roch of Geneva, in a special paper on the subject referred to Alucol as follows: "Colloidal Hydrate of Aluminum adsorbs hydrochloric acid. It has proven in our hands the antacid medicament par excellence, far superior to bicarbonate of soda, magnesia, subnitrate of bismuth, etc."

Alucol acts by forming a colloidal gel in the stomach by combination with any *excess of hydrochloric acid.* The stomach acid is not completely neutralized. Thus a continuance of proteolytic digestion is permitted. Further, Alucol cannot produce a systemic alkalosis as it is not an alkali and is not absorbed.

Alucol is indicated in cases of gastric secretory disturbances characterized by hyperacidity. Reports testify to its undoubted value in the treatment of gastric and duodenal ulcer.

Let us send you a trial supply, together with full literature. Use coupon below.

tablishing a dispensary clinic in connection with the Community Chest Agencies.

"Dr. Cartwright made a motion which was seconded by Dr. Rawles that Dr. Schafer's Committee be instructed to collaborate with the Community Chest and be empowered to establish a clinic at some place mutually agreeable. After considerable discussion by various members, Dr. J. L. Wyatt moved that this motion be amended to read 'For a period of one year'; the amendment was seconded. After some more discussion Dr. Weaver moved that the motion be tabled. This motion was carried by a vote of 15 for and 5 against.

"Whereupon, Dr. Schafer who had already insisted that he and his committee wanted to take some action with the Community Chest on the following morning, presented his resignation which was not accepted. Then there was more discussion, lengthy motions which the secretary could not get down, and most everybody wanted to talk.

"Dr. Dancer moved that Dr. Schafer's committee be given full power to act as they see fit and report back to the society. Motion was seconded and passed.

"In due order a motion to adjourn was made, seconded and passed."

NEBRASKA STATE MEDICAL JOURNAL

The *Nebraska State Medical Journal* is just beginning the sixteenth year of its existence and the eleventh under the present efficient editor, Dr. F. A. Long, who writes editorially in the January issue:

"It has ever been the idea of the present editor that a state medical journal should be the exponent of a cross section of the organized profession it aims to represent; it should publish the articles offered by the profession as space permits, whether highly scientific or mediocre, since they represent the best efforts of the parties and encourage further effort in that direction, which means study; make a prominent feature of editorials by the editor and by members of the profession who wish to discuss medical economic and scientific matters in an authoritative way; that the editor should present to the profession monthly in a terse, graphic manner paragraphs of information, scientific, literary, historical; and that notes of interest about members of the profession of the state should be a prominent feature holding the interest of the reader in classmates, acquaintances and others.

"It is altogether likely that the state medical journal is the most cohesive thing in medical organization today."

Fifteenth Annual Clinical Session

of the

AMERICAN COLLEGE OF PHYSICIANS

Baltimore, Maryland **March 23-27, 1931**

This meeting will be held in Baltimore through the cordial invitation of the Johns Hopkins University School of Medicine, the University of Maryland School of Medicine, the Medical and Chirurgical Faculty of the State of Maryland, the Baltimore City Medical Society, and the further cooperative interest manifested by the various Baltimore hospitals and civic societies.

OUTLINE OF SESSION

Time	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday
A.M.	March 23	March 24	March 25	March 26	March 27	March 28
9:00 A.M. to 12:30 P.M.	Morning free. Registration, Exhibits, etc.	3d *General Session*	5th *General Session*	6th *General Session* — General Business Meeting	7th *General Session*	*Entire Day* in Washington, D. C. Clinics, inspection tours, etc., under auspices of Medical Depts. of Army, Navy, U. S. Public Health Service, Georgetown University. — Full details *not yet* ready.
12:30 P.M. to 2:00 P.M.	Lunch	———	———	———	———	
2:00 P.M. to 5:00 P.M.	1st *General Session*	1st *Clinical Session*	2d *Clinical Session*	3d *Clinical Session*	4th *Clinical Session*	
5:00 P.M. to 8:00 P.M.	Dinner	———	———	Annual Banquet	———	
8:15 P.M. to 10:30 P.M.	2d *General Session*	4th *General Session*	Convocation and Reception to New Members		Free	

The Annual Clinical Session of the College constitutes one of the most valuable postgraduate weeks in Internal Medicine and affiliated specialties conducted on the North American Continent. Members will receive the Program promptly as published, but non-members interested in attending the Session may secure the Program on direct request to the Executive Secretary. Non-members of the College pay a moderate registration fee for admission to the meetings.

The headquarters hotel, the Lord Baltimore, is already engaged to capacity, but suitable accommodations can be secured at any of the following hotels, Altamont, Arundel, Belvedere, Emerson, Kernan, Mt. Royal, New Howard, Rennert, Southern and Stafford.

The Alcazar, Cathedral and Madison Sts., will be general headquarters for the registration of members, commercial exhibits, and all general sessions. Some guest rooms are available at The Alcazar.

GRADUATE EDUCATION IN RHODE ISLAND

The January issue of the *Rhode Island Medical Journal* has an editorial reference to the relation of Brown University in Providence to medical teaching. The University will not establish a medical school, but will help the medical profession in graduate education. The editorial says:

"The University might take it upon itself to become the coordinating agent in organizing a scheme of post-graduate education for practicing physicians. Providence and other adjacent cities possess notable hospital facilities. With the strongest of these hospitals the University is already intimately connected. The scientific services which it has rendered to these institutions and to the public health agencies of Rhode Island for more than a generation place it in a strategic position to bring all of these institutions together and to direct their efforts in an educational enterprise that might well make history. The strength of the University in the biological and chemical sciences which underlie medicine would enable it to make a contribution of its own to such an enterprise which few institutions could surpass.

"In the adoption and publication of the report of which this paragraph forms a part, Brown has definitely gone on record as in favor of the development, under University auspices, of a coordinated scheme of post-graduate instruction for Rhode Island physicians in which the leading hospitals in and near Providence would be involved. Inasmuch, then, as the eminent gentlemen who made the survey and the authorities at Brown agree that such medical teaching is needed and should be developed by the University, it would seem reasonable for the physicians of Rhode Island, who are the people most intimately concerned in this matter, through their representative body, the Rhode Island Medical Society, to express themselves on the subject and to appoint a committee from their number to study the situation."

Achieving Alertness
with this New Camp
All-Over Elastic Support

Much of a man's success depends on his air of alertness and vigor. Also, bad posture and carriage affect general health. To assist men in maintaining alertness, Camp offers this new knitted elastic belt. It acts as a reducer of superfluous flesh, lends abdominal support, helps keep the torso erect—giving a generally correct appearance. The famous *Camp Patented Adjustment* provides the degree of tightness desired. The garment is comfortable and easy to manipulate. Made in different body heights. The therapeutic correctness of Camp Supporting Garments has gained for them the approval of physicians and surgeons everywhere. Sold at the better drug and surgical houses.

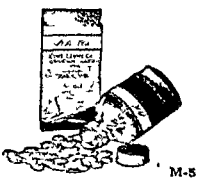
SPOON FRIGHT

—far-fetched and foolish though it may seem to you —causes very *real* anguish to many of your patients. Children and nervous women especially may gag and positively suffer at the mere thought of a whole spoonful of unpleasant Cod Liver Oil.

Your prescription for White's Cod Liver Oil Concentrate is a revelation to these patients—

Just three little wafers—as good as candy—so that for children medicine-time becomes a treat.

And *you* can rely on their taking White's; getting the full Vitamin A and D potency of high-test oil regularly.



Nervousness and wayward irritability in children is often a definite indication for Cod Liver Oil. When you prescribe White's Cod Liver Oil Concentrate you assure the patient of no less than 250 units Vitamin A and 100 units Vitamin D in *each wafer*.

UNTRUTHFUL MEDICAL PUBLICITY IN ILLINOIS

The *Illinois Medical Journal* for January has the following suggestion from the Woman's Auxiliary of the Chicago Medical Society:

"In the September number of *The Delineator*, Celia Caroline Cole presumes to give some sage medical advice; and as treatment 'for the puffy look around the eyes and lines and wrinkled lids,' among other things, she says, 'Eye exercises—spectacles if you have to have them, but better take the eye exercises and have a good osteopath adjust the nerves in the back of the neck and backbone and then dispense with spectacles.' Further on she says, 'use a nourishing cream on the lines and a mild astringent on the puffiness. Learn to rest your eyes by palming, or when you are out in public and can't palm, merely by thinking of lovely things you have seen—feel the eyes relax with pleasure—or by thinking of deep, deep, smoky, floating, velvety black.'

"As a suggestion to the members of the Woman's Auxiliary of the American Medical Association, we recommend that each and every one of them write a letter of protest to *The Delineator* and accompany it with the request that *The Delineator* make suitable amends or cancel the subscription of the writer. If even a few hundred members of the Woman's Auxiliary, with their influence in Women's Clubs, attack *The Delineator* for printing such untrustworthy information as herein quoted, there will be a right-about-face policy adopted by the publishers and owners of *The Delineator*. Intelligent people do not want their favorite periodicals to be dealing out false, unscientific and untrustworthy articles concerning the practices of medical pretenders."

The most unpleasant manifestations of malaise have been frequently allayed by drinking

Poland Water

Physicians have commented favorably on its *bland diuretic* properties for over 60 years.

CULTISTS IN HOSPITALS OF ILLINOIS

The January issue of the *Illinois Medical Journal* prints the following ruling:

"Public hospitals in Illinois cannot exclude any doctors, licensed by the state, whether they are regular doctors of medicine or graduates of schools teaching drudgless healing, Attorney General Oscar E. Carlstrom has advised Dr. Andy Hall, director of the state department of public health.

"Exclusion of osteopaths and other drugless doctors from a hospital at Decatur started a controversy which was carried to Dr. Hall and the attorney general for settlement. Directors of the hospital excluded the drugless doctors by fixing a standard of qualifications which they were unable to meet, Attorney General Carlstrom was informed.

"All physicians who are recognized as legal practitioners by the state board of health shall have equal privileges in treating patients in public hospitals, the attorney general said, pointing to the state statutes.

"Legal practitioners, he added, included all persons who have been licensed to practice medicine, either in all its branches or to treat human ailments without the use of drugs or medicine and without operative surgery. The board of directors of a hospital would have no authority, under the statute, to pass any rules or regulations preventing all legal practitioners from having equal privileges and treating patients in such hospitals.

"The department of registration and education has the power and authority to determine and fix a standard of qualification for those practicing medicine and such power is not delegated to the public hospitals."

A REVIEW OF THE PROGRESS OF THE CONTROL OF TUBERCULOSIS AND ADVANCES IN ITS PATHOLOGY AND BACTERIOLOGY

By EDWARD R. BALDWIN, M.D., SARANAC LAKE, N. Y.

Director, Trudeau Foundation

An address delivered on Oct. 29, 1930, in the Postgraduate Course arranged by the Committee on Public Health and Medical Education for the Counties of Monroe and Ontario.

PUBLIC Health and the Field of Sanitary Education: The relation of the medical profession and especially organized medicine to the control of certain widespread infectious diseases has occupied much attention in recent times. On the one hand is the tradition of the private relation of physician to patient, a precious and sacred function not to be cast away like an outworn virtue. On the other, there is the utter inadequacy of private practitioners acting as individuals to handle the problem of infection in its community aspects. The ideal family is rare where sanitation and intelligence combine to make the infection harmless. Often, when intelligence is sufficient, the means for carrying out preventive and treatment measures are lacking. No disease is more insidious than tuberculosis, or so prolonged and costly to treat. It is not strange, therefore, that gradually and inevitably Public Health has reached down from the state to the county, and from municipality into the school and home. The interesting fact is that so many high minded physicians have themselves promoted this movement as a public duty. Even those who most jealously guard the individuality of private practice have generally regarded tuberculosis in a class by itself for the public health authorities to deal with. This is not of course to disregard the various charlatans and shady brethren who treat tuberculosis as part of the grist to their mills. We all know that they still abound. It is difficult to estimate the number of concealed cases of tuberculosis, except when surveys have been made which usually bring them to light for the first time.

Now the actual effort to control the spread of tuberculosis has been in progress over thirty years in New York State. How much has been accomplished we all know. The antispitting ordinances have been increasingly observed, like our street traffic rules, and they are more and more becoming habits. Public places are less frequently infected, in my opinion, because of the cumulative educational effect of repeated antispitting signs. Again, we no longer observe the consumptive street loafers commonly seen in most communities in the early nineties. Probably they are mostly in institutions or resting at home. Certainly many are under some form of advice by nurses or treatment by their doctors, and use care with their sputum.

What has been the result on the prevalence of tuberculosis? The death rate is reduced by one-third at least. Have we a right to say that the disease has diminished chiefly if not wholly because of the present day isolation of patients and sanitary care of the sputum, or is the higher standard of living and good housing more to be considered?

I think most students of tuberculosis agree that the major part of the decreased mortality from tuberculosis is the effect of prophylactic measures, including the isolation of the open cases in hospitals or in the home. It is futile to try to dissociate the various factors and measure them. Both the automobile and the vacuum cleaner, for example, are involved in the problem; the first by relieving the fatigue of the worker from walking and the outdoor life promoted for shut-ins, the second by removing infected dust without stirring it up for the family to inhale.

Surely much of the hardship of life has been softened in this machine age, with all its faults, because of shorter hours and labor-saving machinery.

Unquestionably the education of the lay public is the outstanding accomplishment of our generation. The National Tuberculosis Association may be regarded as the agency of the greatest health propaganda ever launched, and it has served as a model for several other health organizations. It has accomplished another thing, however imperfectly, and that is the education of many medical men through its publications, lectures or

exhibits—a task practically impossible for medical schools.

Importance of X-ray Diagnosis and Sputum Examination: The busy private practitioner has little time to learn refined methods of diagnosis and little educational opportunity to study tuberculosis. He has, however, learned as well as the patient, that the physical examination of the chest is often insufficient in the practice of specialists, who now resort to the *x*-ray in nearly every case. Further, he knows it is quite as important to have a sputum examination as it would be to have a culture made in suspected diphtheria. Indeed, the time may not be far distant when both procedures will be required by law, with penalties or damage suits for neglect. We are rearing a structure of medical knowledge that is far over our present practice, and the public knows it, especially with reference to tuberculosis.

School Surveys: At the present time the public school is the focus of the efforts to find and control infectious cases. We have still far to go in this study but a good beginning has been made.

The great value of school examinations for tuberculosis lies in the fact that adolescence appears to be a critical age for the beginning of pulmonary tuberculosis. This statement will not come as a surprise to the older family physicians, who long ago watched solicitously over the developmental age of children among their clientèle. I think that no one could be in better position to do this than these older men, if modern diagnostic methods were universally accessible and employed. This objective can only be reached by systematic health examinations, the subject of so much agitation at the present time. The lay public is being made health conscious in many ways and it may be that the price to be paid for the recognition of latent tuberculosis will be a crop of hypochondriacs, which wisdom in prognosis will be needed to counteract. Here again is where a family physician should be indispensable.

Wholesale examinations by tuberculin tests and the *x*-ray are the logical steps to trace the unsuspected cases to the home, as has been done in Massachusetts and in several of our own communities. To quote a gifted Canadian colleague, Dr. David A. Stewart of Manitoba: "The search among contacts for early disease needs, as Burton Woods has it, even more than the imagination of a poet, the ear of a piano tuner, and the touch of an osteopath"! "Tuberculosis can be, like an iceberg, only one-tenth visible and nine-tenths invisible. . . . The best eyes and ears so far devised for the submerged nine-tenths of tuberculosis is the *x*-ray plate."

The work of Dr. Walter L. Rathbun in Chautauqua County is one of the most instructive in this connection, because he was able to trace so many bacillus carriers by examining the school children with the *x*-ray. The presence of a carrier at home is thus frequently uncovered.

Thus we must look ahead to the general use of the *x*-ray in diagnosis of chest conditions, and it must be placed at the disposal of those who cannot pay for it themselves. The vast improvement in the technique of *x*-ray photography should eventually make the mastery of this essential method within the reach of more physicians. Frankly, such an outlook is far from being realized very soon, except in favored communities.

It is at present known that the control of tuberculosis varies widely in different states and cities. If we succeeded in establishing an ideal control in one area, as is being done for cattle by the "accredited herd" system, we should then need to quarantine against imported tuberculosis among new settlers, or even among visitors, an obviously impossible task with a disease so readily overlooked. There is however an attempt to do this very thing in the Belgian Congo where the danger of a veritable scourge of tuberculosis exists among the black natives when the disease is carried to them. The prospect of abolishing tuberculosis in the mass does not appear favorable, yet every patient removed from the home during the infectious stage of open disease makes a definite break in the many contacts.

Unsolved Problem of Supervised Work for Arrested Cases: When the health departments of cities and counties are properly supported much will be gained for tuberculosis, for the majority of patients need more than temporary hospital or sanatorium care. I refer to the employment of arrested and chronic cases. The great need now unfulfilled in our tuberculosis program is, in my judgment, for some remunerative work for these cases, preferably in an institution and supervised by sanatorium or hospital staffs. Such earning capacity as patients possess is often not utilized, and this leads to despondency and loss of initiative, as in our prisons. It is a knotty problem and yet so long as chronic cases are discharged to their homes to shift for themselves, it is discouraging to the best results obtained by treatment.

Advances in the Knowledge of the Tubercle Bacillus: The rehearsal here made of the way in which tuberculosis is steadily being reduced obviously does not cover all the steps. There have been many advances in the knowledge of the disease itself. The bacillus has been subjected to intimate study, both in culture and in its chemical nature. Formerly it was held that the three principal varieties, human, bovine and avian, were distinct varieties: now there are known to be intermediate forms that are less sharply defined and yet cause disease. Still other acid-resisting bacilli have no power to infect animals, though they seem to be distant relatives of the pathogenic- or disease-producing forms. It is on the weakened or modified tubercle bacilli that various

methods of immunization have been based

Inadequacy of Vaccination against Tuberculosis The latest proposal for the wholesale vaccination of infants by Calmette utilizing a weak bovine inoculation, has had a wide use in Europe There are grave objections to depending on this or on any other method of vaccination against tuberculosis In the first place no evidence has been brought out that a complete protection can be conferred and after a few months the slight resistance which at first may be created, dies out again Thus a false sense of security is likely to be engendered The very protection itself is caused by tubercles and vanishes when they disappear or heal completely, whereas if they persist the vaccine cannot be non pathogenic There are also some experiments which show a revival of the virulence of the vaccine Advocates of vaccination as a solution of the problem of exterminating tuberculosis seem to overlook the fact that if mild infections could protect against severe ones, we should long ago have seen the disease disappear spontaneously from natural infection which is so nearly universal

The possibility of doing some good by vaccination is nevertheless to be admitted for during the first two years of life natural infection may be very serious where exposure is inevitable Even sterilized vaccines made from virulent bacilli, are slightly protective and safe Trials are being made of this method both at home and abroad On the other hand tuberculins do not serve this purpose In all the years that tuberculin has been used in diagnosis and treatment, none of the many kinds has been found to give any immunity Its continued use as a therapeutic agent is largely restricted to non-pulmonary tuberculosis such as that of the eye skin and old sinuses from suppurating joints, lymph glands, etc

Advances in Knowledge of the Course of Infection Pathology has also revealed new facts concerning tubercle The conception of a primary lung or gland infection through the intestine, followed by healing and secondary or superinfection, prevails today While childhood is frequently the period of successive infections which cause little disturbance of health, during early maturity they take on a serious form in the apex of the lung Here is where the clinical disease most often commences, whether from extension of the original primary focus or a newly acquired infection In most cases it is impossible to trace early apical disease to any single exposure, usually prolonged and intimate contact in the home is to be looked for Whatever the sequence of events, the patients begin to have the first symptoms at an age when life is full of interest and excitement, when youth is prone to make light of them

It is not surprising therefore that a first examination discloses a cavitation already present near the level of the clavicle The ear scarcely will detect these early cavities and they frequently go on to healing or extension before being recognized by the x-ray

Tuberculosis develops at all ages and frequently complicates old age, when for the most part it is a mild disease In middle life it is often a relapse from a former disease, unrecognized and never completely healed On the other hand the development may be due to heavy strain and exposure to infection for the first time Many occupations are predisposing, especially dusty ones and those causing mental strain and loss of sleep Climatic conditions have lost some of their meaning as predispositions, whereas environment and frequent exposure to infection have assumed prime importance

Causes of Lessened Prevalence of Tuberculosis It is now apparent that the great diminution of the disease since 1920 is closely related to the markedly better standard of living, shorter working hours and decreased alcoholic excess, with its associated evils Among the important predispositions, one that has become a serious industrial problem is the inhalation of silica dust in the trades like granite cutting carborundum and tool grinding It can be experimentally shown that animals develop a severe tuberculosis after exposure to stone dust containing quartz and any other form of silica Legislation affecting these dangerous occupations has already been enacted in some states and foreign countries

It would be interesting to refer in more detail to the pathological studies showing the relation of tuberculous lesions to relative immunity and its associated allergy The latter being largely the cause of the inflammatory effects of the invasion of healthy tissue in patients, is undoubtedly responsible for what is known as the exudative type of tuberculosis and also for the pleural, peritoneal and joint effusions It can act favorably in causing absorption of fresh tubercle, but often destructively as in caseous pneumonias

Thus nature is provided with a two edged sword, and in overaction we see harmful effects Enough has been mentioned, I think, to show that steady progress has been going on in the fundamental study of tuberculosis, its cause and effects

New interpretations are being made of older observations such as the pathological findings in chronic fibrous forms of the disease which offer a favorable outlook for long life often for a full and active life Clinicians will ask how they may distinguish between such and the more unstable forms of the disease Unfortunately, one may change into the other without apparent cause, and good judgment must always preach "safety first

In conclusion I can but urge the general practitioner to act on the earliest suspicion of symptoms and to educate his clients to the point of doing the right thing first, at whatever sacrifice

THE APPLICATION OF HIGH-FREQUENCY CURRENTS IN OTO-LARYNGOLOGY*

By LEE M. HURD, M.D., NEW YORK, N. Y.

HIGH frequency currents are also known as diathermic, endothermic, electro-surgical, and electro-thermic currents. The types of currents are: 1. Coagulation, bi-polar or d'Arsonval, which destroys the tissue in proportion to the strength of the current plus the length of time it is in contact with the tissue. 2. Knife current which is also bi-polar. This current divides the tissues by molecular dissolution, just slightly searing the cut surface. 3. Desiccating, mono-polar or Oudin. The coagulating and desiccating currents largely overlap each other in their actions.

To use these three currents, the operator does not need to know that the knife current is undamped and of much higher frequency than the other two, or that the Oudin has a higher voltage with a frequency between that of the knife and coagulating currents. His only concern is in regard to the character and effects of each current in their uses, and whether the machine he has or intends to acquire, will give the desired output in a satisfactory manner. Practically, all three currents, of a satisfactory quality, can be combined in one outfit at a reasonable price.

The coagulating current should destroy tissues quickly under complete control of strength, from the very lightest work to heavy destruction with perceptible faradic current, and also give diathermic heat. The knife should cut quickly and smoothly with only the slightest searing of the divided tissue. There should be no sticking or sparking, which would char the tissue. The Oudin, or mono-polar current, mainly used for surface desiccation, should be produced with a spark varying from the most delicate to very heavy.

There is no definite reading of the milliammeter or the dials, which will mean the same effect in every patient. You know what action you wish to produce and you learn by practicing on meat, what setting your particular apparatus requires. It is comparable to driving an automobile or playing a musical instrument. You learn by experience the limitations and capabilities of your apparatus.

I have received the impression that it is nearly painless, but on the contrary, if an amount of current is used, sufficient to get fairly quick results, it is painful, not only at the time of the treatment, but afterwards. It is not, however, as painful as the older methods of removing tissue about the throat.

It is also stated that endothermy is bloodless. This is true at the time of the operation, but when the slough comes away, there may be bleeding, and great care should be used not to coagulate near the vessels, as it is possible to destroy part of the vessel wall, and later have a very serious hemorrhage. Near bone or cartilage great care should be used, otherwise necrosis results. Circumstances may be such that you are prepared to have dead bone after endothermy of the soft tissue overlying the bone or cartilage.

One of the instruments that makes the application of endothermy possible in oto-laryngology is the snare with either the cutting or coagulating current. The indications for its use are the same as for the cold wire snare, except on bone, unless you are prepared for a protracted healing of the bony necrotic base. The action of the snare on the tissues depends on the strength of the current used, the size of the wire, the size of the loop, and the speed of closing the snare.

Surgical diathermy can also be applied by the means of variously shaped instruments which have been designed to reach the deeper parts of the nose and throat, and which are insulated up to the tip. The metal tips are either sharp pointed so that they will penetrate for deep coagulation, or dull for surface coagulation and desiccation. Ordinary sewing needles in a standard handle are used, for the application of the current in easily accessible locations.

The coagulation current works as well and usually better than the methods previously used, in the following conditions:
1. Dividing nasal synechias. By the old methods, there was a great tendency for the adhesions to reform, which required treatment by placing some material between the raw areas. With coagulation this tendency of the tissues to grow is overcome, because the coagulum remains in place between the two surfaces, until they are healed. 2. In reducing hypertrophied turbinates. 3. Destroying post-operative granulations in the nose and throat. 4. In epistaxis, the mono-polar current, Oudin, will close vessels much better and more quickly than galvano-cautery or chemical caustic. In fact hemorrhage anywhere in the nose or throat, from the soft tissues, if it can be reached, can be easily and quickly stopped with either the coagulating or the desiccating current. 5. Destruction of polyps.

The Removal or Treatment of Tonsils: Knife current dissection is claimed by Dr. Leroy Thompson[1], to have great advantages. I have tried this method, found it difficult, and doubt

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

whether it is superior to standard surgery The Sluder snare method, reported by my associate Dr. W. W. Morrison,[2] using the knife or coagulating currents is still in the experimental stage; it appears to have the advantage of being bloodless, and may destroy enough of the capsule in the fossa to destroy the lymphoid islands, that later develop and thus spoil an otherwise perfect result.

A question that is still unsettled is whether or not there is considerable coagulation in the fossæ, even when at the time of operation the fossæ show only slight searing.

Treatment with View to Destroying the Tonsils in Situ: 1. By coagulation multiple small punctures of the tonsil are made, each puncture destroying an area 3 to 4 m.m. in diameter. On the average tonsil it will take about 10 series of punctures to cover the surface. Each of these will result in slough 3 to 4 m.m deep, and annoying dysphagia for about a week. The procedure has to be repeated at intervals until the capsule is reached. By measuring the tonsillar depth and dividing by 4 m.m., the answer is the number of times the tonsil will have to be treated.

2. Mono-polar (Oudin). If the tonsil is punctured with the needle and sufficient current is used, the effect is the same as above when the coagulation current is used. If the surface of the tonsil is sparked, there will be only superficial desiccation, which is a still longer process, before the entire tonsil will be destroyed. It is stated that there is less liability of hemorrhage with the Oudin because the slough comes away gradually, whereas after coagulation the slough separates in toto. I have seen bleeding from both Oudin and coagulation currents, in tonsil work.

SUMMARY: 1. The theoretical advantage of less infection and bleeding. 2. Removal of tonsils with the endotherm snare may have a future because there may be less bleeding. A question which remains to be answered is how the tonsil fossæ will react to the action of the current. Furthermore there is a tendency toward exuberant granulations in the fossæ. 3. The destruction of the tonsil with coagulating and Oudin currents has a place where surgery is contra-indicated, otherwise it has no future. 4. Post-operative remnants of tonsil tissue, which sometimes appear after what seemed a perfect operation, and by remnants I do not mean cases where half a tonsil remains, but the so-called lymphoid islands, which are generally a half to one centimeter in diameter and about half a centimeter in depth, may be destroyed at one sitting. This is possible because the area and depth are definitely known, and the method has the great advantage over standard surgery, of being bloodless, with less after-pain, and can be quickly and easily done in an office treatment. This pertains to the stump of the lower tonsillar pole as well. 5. Adenoid remnants, especially at the side of the nasopharynx can be more accurately removed by coagulation. The hypertrophied lateral pharyngeal folds, and the post-pharyngeal lymphoid follicles are also more satisfactorily eradicated by coagulation.

There is, in the fossa of Rosenmüller, a condition, not generally recognized, which causes recurrent O. M. S. A., acute naso-pharyngitis and rhinitis. This is a chronic inflammation in the lymphoid tissue of the fossa. I have seen fossæ that were three-quarters of an inch deep. By the old method of biting this infected tissue out with forceps, or dividing the bands that so frequently run across the space, the results were unsatisfactory. Destruction of this infected tissue and these bands, can readily be done with the endotherm. There also may be an associated hypertrophy of the tubal tonsil, which appears as a series of follicles, each one of which can be pierced with the needle and destroyed.

The hypertrophied lingual tonsils and varicose lingual veins can be destroyed with less pain and no hemorrhage.

The endotherm knife may be used to advantage over older methods, in opening abscesses. It is especially advantageous in destroying cysts, first opening them either by a linear incision or removing a circular piece or button from the wall and then desiccating the cyst wall. This is much more certain of success than attempting to disect out the lining membrane of the cyst.

The field of operation should be anæsthetized with novocain or by topical application of alypin. If the area to be treated is extensive such as a so-called secondary tonsil and adenoid, a general anæsthetic is necessary.

We have worked out a practical and safe method to guard against explosions from ether. The patient is started as usual with gas-oxygen and ether, and when the time comes to use the endotherm, the ether and anæsthetizing apparatus are removed to a safe distance, the patient allowed to come out of the anæsthetic enough to establish the eye reflex, and then lightly held with chloroform, as long as the endothermy is in use. If there is any further surgical procedure, the anæsthetist reverts to ether.

In conclusion, the endotherm apparatus may also be used very successfully for the administration of diathermic heat. In cases of pain and tenderness from acute frontal and maxillary sinusitis, ear infections and otitis serosa, a small metal plate is fitted over the painful area of the forehead or cheek, with a large

electrode on the arm or back. The heat within the tissues, so produced, will regularly relieve the pain, and is the only method I have found that will do it so promptly.

DISCUSSION

By John McCoy, M.D., New York, N. Y.

We have just listened to a very practical discourse on Diathermy. As Dr. Hurd has said, we have three types of current, namely, the cutting type, the coagulating type, and the desiccating type.

Previous to the introduction of high frequency currents we had nothing but Faradic and Galvanic currents which always affected the muscles. The introduction of the high-frequency current is such as to give a very high frequency which exceeds the limit to which the muscle tissues respond. I was very glad to hear Dr. Hurd say that in using this current it was neither painless nor bloodless, because I have found about the same thing, although the more I use the current the less painful and the less bleeding I get.

With regard to the use of a snare there have been several types advocated, but as none has proved a complete success I have not adopted any one of them.

I have found the current very useful to keep the Sphenoidal Sinus open after an Ethmoid and Sphenoid operation.

In the removal of Tonsils I have used the cutting current where the patient has had a long coagulating time. At present I am using the puncture with the coagulating current.

It is very useful in removing Adenoids from the Fossa of Rosenmüller and in Hypertrophied type Tonsils. It is also useful in opening Abscesses and destruction of Cysts.

Medical diathermy is very useful in relieving the pains of Sinusitis over a Frontal or Maxillary Sinus, or an acute ear.

Growths: I have introduced the coagulating current to remove very bloody Naso-Pharyngeal Fibromata. I have also used it in non-malignant growths in the Larynx. Also, in beginning of Cancer of the Larynx after Thyrotomy.

PHYSICAL THERAPY IN COMPENSATION WORK*

By HOMER J. KNICKERBOCKER, M.D., F.A.C.S., GENEVA, N. Y.

IT MIGHT be well to state at the beginning that the speaker is not a Physical Therapeutist. He has, however, had the opportunity of sitting on the sidelines and in the grandstand, even reserved seats, from which position observation was possible along certain lines which constitutes the basis of the paper to be presented.

In September, 1928, our chairman, Dr. Richard Kovacs of New York City, presented before the fifth International Medical Congress for Industrial Accidents and Occupational Diseases at Budapest a paper entitled Physical Therapy in Traumatic Conditions, which was printed in the *International Clinics*, Volume 4, Series 38. The opening paragraphs of this article are so apropos to the subject of this paper as to make their quotation desirable. Dr. Kovacs said:

"The use of physical measures in acute, subacute and chronic traumatic conditions forms an essential part of their modern treatment. Following the impressive object lesson furnished by the extended application of physical measures during and after the Great War, physical therapeutic departments have been established in the United States of America in connection with industrial plants, insurance companies, and in all progressive hospitals treating traumatic cases. Unfortunately, the equipment and the actual operation of these departments varies very considerably. At the low end of the scale are some industrial clinics organized on an entirely commercial basis where "baking and massage" is ordered as a routine in all cases of injury and applied by a masseur or nurse, often perfunctorily and without competent supervision. At the upper end of the scale are well organized departments equipped with all the modern measures of physical therapy, including electrotherapy, thermo- and hydrotherapy, phototherapy, massage and mechanotherapy, and operated under the direction of a skilled medical director and in organic cooperation with the surgical and the other departments of the hospital or industrial plant. Results differ according to these divergent standards, and it may be well to state that the overplaying of physical therapy as an added measure of revenue by a few commercially inclined organizations and physicians already threatens a setback in the employment of this important part of therapeutics. A recent report of the Com-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1930.

mittee on Traumatic Surgery of the American College of Surgeons states that in the large majority of cases physical therapy as now rendered is of little value In reply, Granger emphasizes that an analysis of this report makes it evident (1) that in many cases the surgery was so poor that treatment by physical therapeutics or by anything else could not overcome this handicap, and (2) that in many cases the physical therapy to put it mildly, was unintelligently prescribed and applied

"The practical application of physical therapy to traumatic conditions demands

"1 A complete diagnosis in every instance The careful initial examination should always include definite findings as to (1) state of injury or repair contour of limbs and joints conditions of scars, measurement of circumference union of bones, (2) state of function range of motion in joints, strength of muscles (grip testing etc) (3) special examinations such as electrical and sensory tests in nerve injuries Roentgenograms are well nigh indispensible in most instances

'2 Consideration of the existing pathology or functional disability and the selection of the appropriate physical measures to meet the individual case It is not a question of a certain apparatus to be applied to a certain diagnosis, but rather of a certain physical agent or combination of agents to the existing condition Physical therapy should by no means be confused with apparatotherapy

'3 Periodic check up of the results by frequent examinations which should always be carefully recorded, together with such changes in treatment as the conditions warrant Physical therapy is only perfunctory when a patient continues to receive the same treatment for months without any attempt to ascertain progress

"4 Periodic consultation with the referring surgeon This will enable the surgeon to appreciate the possibilities and limitations of physical therapy

"5 A definite procedure for discharging patients and recording and results"

If it is necessary or advisable to have a complete history and physical examination of a patient before submitting him to a major surgical operation it would seem that at least a general familiarity with conditions presented in such history and examination should be in the possession of the physical therapeutist before any treatment is started Observation would indicate that such is not generally had The attending medical man too often treats or refers his case for physical therapy with only a meager knowledge or description of the injuries sustained and a request for reconstruction thereby reducing the physical therapeutist to the standard of a technician who has authority by the reference of the case to treat it in whatever manner he thinks best This is manifestly unfair to the physical therapeutist and frequently prevents him from getting results such as he would desire as well as handicapping him in the choice of modalities Any form of treatment which does not give results commensurate with the inconvenience, suffering and expense cannot be considered as being successful The haphazard reference of cases encourages perfunctory treatment, leads to abuses and discredit to all concerned That this has happened to the physical therapeutists is evident from the attitude of the carriers whenever such treatment is suggested

When we consider the number of high pressure apparatus salesmen there are on the road, the proverbial gullibility of practitioners of medicine when it comes to something new and the few places available where a doctor can get unbiased information and instruction relative to the application of physical therapy, it is no wonder that the carriers feel that in a large percentage of cases that they are not receiving the benefits for which they are paying when physical therapy is used At a meeting held December 6th, 1929, in New York City at which were present the various members of the State Committee on Physical Therapy and representatives of the insurance carriers operating in this state, a questionnaire was discussed The first question, "Is physical therapy as administered by the average doctor handling your cases giving results commensurate with the cost?" was uniformly answered no In the discussion it was brought out that while there were some real physical therapeutists there were so many medical men using physical therapeutic methods without definite knowledge as to their method of application, the selection of cases or what was to be expected that the insurance group felt that however honest the medical profession might be the end results as a whole amounted to defrauding the insurance carriers far beyond the benefits obtained Someone has said that "it requires an unusually honest doctor to refrain from overtreating a patient when he realizes that the pay is good and assured" There is also one other condition which might apply, that is an unusually busy doctor but if the excess of business consisted in keeping them coming of course that would not apply

To offset this condition many of the carriers as well as numerous large employers have established their own industrial clinics with part or full time medical supervision, technicians and nurses Unless we as a medical profession can deliver results measurable in dollars greater than the cost of production we will soon be faced with a situation whereby large employers and carriers will establish their own facilities for treating their injured workmen, all of which will make a decided inroad into the incomes of pri-

vate practitioners located within the area served by such clinics. We have diligently fought for many years against state medicine and unless we can see into the future and rectify our shortcomings I anticipate that sooner or later we will be faced with corporation medicine. In many of the large industrial centers such a condition already prevails, much to the detriment of the private practitioner. It is obvious that the remedy lies within ourselves and rests heavily on each individual to see that his particular work along these lines is the very best that he is capable of doing and fully worth the price he charges.

Numerous manufacturers of physical therapy apparatus conduct so-called courses of instruction which are in reality nothing more nor less than sales promotion. They do a lot of advertising, gather in as large an audience as possible, make extravagant claims and overload the customer with what in many instances is a questionable office ornament devoid of genuine therapeutic possibilities, all out of proportion to the cost. Itinerant lecturers cover the country from one end to the other giving courses in physical therapy and other things at so much per capita attendance. Examination of this class of instruction shows that as a whole it is very low grade, overoptimistic and in many instances actually dangerous. It is conducted entirely as a revenue getting proposition without regard to any extent of the character of the individuals instructed. A survey of the state was made with the result that it was found that no medical college was giving undergraduate courses in physical therapy which were considered adequate. New York University and Bellevue Hospital Medical College give no course in physical therapy to physicians, but do give a course to the School of Education, at Washington Square, in conjunction with the Hospital for Ruptured and Crippled, which course is open to technicians who are candidates for the physical therapy license. Columbia University gives an elective course during the third and fourth years of undergraduate work one hour each week during each quarter. It offers also an extension course for graduates of medicine at Mount Sinai Hospital and Montefiore Hospital. Cornell University gives only one morning a week for four weeks to groups of undergraduates at the Hospital for the Ruptured and Crippled. New York Homeopathic Medical College and Flower Hospital give a course of eleven hours of clinical and eleven hours of didactic work to the third-year students and also to the senior class. The Polyclinic Medical School and Hospital of New York offers a four weeks' course daily on the theory and practice of physical therapy in all departments of medicine with four weeks optional additional clinical work. This course is given regularly every two months. The New York Postgraduate Medical School and Hospital has no organized course in physical therapy. Some instruction is given in the orthopedic seminar. The Albany Medical College gives undergraduates some instruction in the courses on Therapeutics and Orthopedics. Syracuse University gives fourth-year students one hour a week of didactic work and two-hour clinics weekly through a four-week period. The University of Rochester School of Medicine and Strong Memorial Hospital give no definite course in physical therapy. The University of Buffalo gives a course to third-year students in which sixteen hours of instruction are equally divided between recitations and demonstrations. It is apparent that the establishment of at least two thorough courses in physical therapy available to the practitioners of the state should be had, at as early a date as is practicable. Your committee has already gone on record in a statement advocating that no physical therapy apparatus of any consequence be acquired by any practitioner until he has acquired through some competent source sufficient knowledge of the application of modalities, their indications, etc., as to warrant his presuming to do physical therapeutic work. If this instruction were had much less apparatus would be purchased and better work done and much of the dissatisfaction of the carriers would be eliminated.

Physical therapeutists are many times hampered by having referred to them for reconstruction cases which present palpable evidence of bad surgery. The surgeon too often hands the case over to the physical therapeutist and expects him to pull the surgeon out of the hole. Fortunately in many of these instances good physical therapy will minimize what would otherwise be a high percentage of award provided the proper method of treatment is carried out. For the information and protection of all parties concerned adequate records of the case as an individual, his particular condition when received for treatment with a complete description of the lesion and all that pertains to it should be made before treatment is begun. Any treatment which continues without a periodic survey for the purpose of estimating progress is open to question. What this period should be will of course depend upon the character of the trouble, but it is generally conceded that six weeks should be the maximum period of treatment before estimation of progress is made. In all probability two weeks would be the minimum. How often treatments should be administered or for how long is a matter of individual choice.

Adequate reports to carriers at relatively frequent intervals are appreciated by them. To these reports they are undoubtedly entitled that they may set up proper reserves against the disability of the individual case, be informed of its

progress and know what to expect so that they can put it on for hearings at the proper time It is a well known fact that compensation cases require on the average more treatment than similar cases in private practice A recent analysis of an equal number of unselected private and compensation cases, a total of 2,000 cases made by Dr K G Hansson and Dr F J Marjey of the Hospital for the Ruptured and Crippled in New York City shows that compensation cases require approximately twice as many treatments as private cases If this be true in a large clinic where constant supervision checking up and weeding out is practiced what would the ratio be if these cases had been treated by a poorly equipped enthusiastic private practitioner physical therapeutist possessed of an elastic conscience? There can be no denying that such people do exist and it is little wonder that the carriers are dissatisfied Many practitioners are in the habit of sending their physical therapy work to some qualified or unqualified physical therapeutist who may or may not be licensed and whose sole source of livelihood depends on how much work he can get and what he can get for it Too much indiscriminate handing over of patients is going on Whenever a practitioner hands over a patient to a technician he assumes a moral and legal responsibility for that technician's conduct so far as the medico legal aspects are concerned It therefore behooves us to select with the greatest of care those to whom we would send our patients and it also becomes our duty to check up at regular intervals for our own edification and satisfaction as well as for the purposes of reports to the carriers whenever indicated Treatment prolonged beyond the stage of advisability, improperly or inefficiently given, becomes a responsibility of the referring physician, a point which he seldom realizes as much as he should To whom, when and how long and for what he sends his patient should be clearly indicated that he may justify the results Nowhere in the practice of medicine do we come in contact with malingerers as much as we do in its relation to workmen's compensation Repeated appearances in compensation court often has the result of the development of a very clever malingerer whose detection is difficult

In the treatment of this class of individuals the physical therapeutist has an opportunity for real service Upon him as well as the physician in charge of the case must rest the responsibility of detection because their personal interests, as well as those of the carriers are involved Medical testimony in favor of claimants who are later found to be malingerers does not improve the standing of the physician so testifying in the eyes of his professional brethren or his potential employers, the carriers It therefore behooves us to guard our statements and make sure that they are based on facts whenever we are called as medical witnesses

In conclusion to make physical therapy successful we must have *first*, the very best possible surgical job that the case can receive *Second*, we must have a diagnosis of the lesion presented, sufficiently broad knowledge of the general condition of the patient and all that pertains thereto so that we may be in a position to see the case as a whole and not confine our efforts in the treatment of an individual part without knowing the limitations of the case *Third*, we must select that proper physical therapeutic modality which is best suited to the particular case, apply it with intelligence, diligence and skill *Fourth*, we must have adequate records from the beginning of the treatment through to the final check-up which will show some progress in order to make the treatment worth while Failure to make progress must indicate futility or improper treatment *Fifth*, we must make adequate reports to the carriers so that they may be in a position to know what is going on and govern themselves accordingly *Sixth*, we must be absolutely honest with our patients, the carriers and to ourselves, as by this method only can we merit confidence and the success which we hope to obtain

---

ARTIFICIAL PNEUMOTHORAX AND PHRENICECTOMY IN THE TREATMENT OF PULMONARY TUBERCULOSIS

By HERBERT F GAMMONS, M D, AND ARTHUR N AITKEN, M D LOCKPORT, N Y

PHRENICECTOMY as a treatment for pulmonary tuberculosis is increasing in popularity while artificial pneumothorax is still a very important factor in the treatment of this disease

Therle[1] says phrenicectomy is valuable in unilateral and basal lesions in basal adhesions preventing full collapse with pneumothorax and preliminary to thoracoplasty

O'Brien[2] says in cases where either pneumothorax or phrenicectomy may be used, phrenicectomy is more desirable

Bridge and Bly[3] in a series of 60 cases obtained very good results Bridge feels that

Read at the Annual Meeting of the Medical Society of the State of New York at Rochester N Y June 3 1930

patients who get good results from phrenicectomy are not handicapped in doing their regular work.

Mayer and Leetch[4] obtained good results in decreasing the size of cavities of long standing that had resisted other forms of treatment.

Wells[5] obtained beneficial results in approximately two-thirds of a series of 271 cases and found that it gave good results more often in apical than in basal lesions.

We wish to report on a small number of cases treated by phrenicectomy and to express our opinion of the value of this form of treatment compared to artificial pneumothorax and also, of the combined treatments in certain cases.

In a county tuberculosis sanatorium we are naturally unable to pick our cases and are confronted with the problem of many advanced cases who are not ideal for any form of compression treatment but who will die if something is not done. Then, too, if we can relieve many of these advanced cases of troublesome symptoms not expecting an arrest of the disease, we feel that we have accomplished some good.

We are mindful of a number of patients who have taken artificial pneumothorax and who have developed serious and oftentimes fatal complications such as empyema or spontaneous pneumothorax. We also find many patients who have adhesions which prevent a satisfactory collapse of the lung. Also we find a few where the location of the lesion is at the base of the lung and the rest of the lung is normal. In this latter type it seems poor policy to compress the whole lung when phrenicectomy will often collapse the infected area only and leave the good lung tissue to functionate.

Many cases treated by artificial pneumothorax get so much contraction of the lung by the time the treatment is to be stopped that the lung will not fill the pleural cavity without marked displacement of the other organs unless the nerve operation is performed. Also there are many patients taking pneumothorax who have a flexible mediastinum or depressed diaphragm that interferes with a satisfactory compression of the lung in the diseased area.

There are some cases with multiple cavities and not any toxic symptoms where the mechanical effect rather than the effect of overcoming toxæmia are desired and in such cases the nerve operation we feel should be done first. On the other hand when there is a large amount of disease with marked toxæmia or profuse bleeding with the contralateral lung in good condition artificial pneumothorax will produce the quickest relief of symptoms. When the contralateral lung is much involved, but not apparently active, the nerve operation is to be desired as there will not be as much work put on the contralateral lung with this treatment as there will as a result of artificial pneumothorax.

In cases of long standing with cavitation apparently near the surface, especially at the apex, adhesions often prevent a collapse with artificial pneumothorax, and there is the possible danger of a spontaneous pneumothorax if much pressure is applied. These cases should, in our opinion, be treated by phrenicectomy.

During the past year 31 patients at the Niagara Sanatorium have been treated by phrenicectomy, 28 of these were far advanced and 3 moderately advanced; 10 were right side and 21 left, the youngest was 19 years and the oldest 55 years. The operations were performed by Dr. Edgar Phillips to whom credit is due for the good results we have obtained. In this series 11 phrenicectomies were done as a preliminary treatment to thoracoplasty. Seven of these 11 were failures with pneumothorax on account of unsatisfactory collapse. One was unable to take pneumothorax on account of adhesions and 3 were not given pneumothorax but apparently had adhesions. Six of the 11 have had thoracoplastic operations, 2 have improved so much they may not need it and 3 are being observed on account of the condition of the contralateral lung although the operated side is improved. In 5 of the 31 cases, phrenicectomy was done to relieve adhesions after pneumothorax had been given and there was an improvement in 4 cases, with rapid disappearance of pleural effusion in 2, with no improvement in one who had a basic cavity that was not improved by artificial pneumothorax. This patient had a spread of the trouble to the contralateral lung and we feel that if she had had the phrenicectomy in preference to the pneumothorax she would have been benefited. This is the only patient of the 31 that has died and her death was not caused or hastened by phrenicectomy.

In one case the object of the phrenicectomy was to relieve a bronchial-fistula resulting from a post-pneumothorax empyema and preliminary to thoracoplasty. This bronchial-fistula was relieved but has reopened. In 3 cases the treatment was given to relieve symptoms such as severe pleurisy, persistent hemorrhage and excessive cough. All of these 3 showed improvement of their symptoms. Two of them could not take artificial pneumothorax on account of adhesion and the other 1 was not tried on account of the disease in the contralateral lung. In 3 instances the operation was performed to obliterate or decrease size of cavities with improvement in all. In 9 of the 31 cases phrenicectomy was performed

with the hope of arresting the disease All of these 9 have shown very good improvement except 1 who had so many adhesions that the diaphragm did not arise and 1 who has an increase of trouble in the contralateral lung One, a basic lesion that was spreading is apparently arrested

White it is impossible to determine beforehand, whether or not adhesions are present that will prevent a satisfactory collapse with artificial pneumothorax we feel that phrenicectomy is indicated in the following

(1) *In the chronic practically unilateral case* without acute symptoms
(2) In a chronic case where there is a moderate amount of involvement in the contralateral lung, which is improving or not spreading.
(3) In all basal lesions that are unilateral and *not improving*
(4) In cases with apical cavities near the surface where there are probably adhesions
(5) As a symptomatic treatment for hemorrhage, persistent pleurisy and severe cough, where artificial pneumothorax cannot be given *either* on account of adhesions or too much involvement of the good lung
(6) Preliminary to thoracoplasty
(7) To stabilize a flexible mediastinum during pneumothorax treatment
(8) To decrease the size of a pleural cavity to allow for contraction of a lung when stopping pneumothorax
(9) In cases where pneumothorax may be indicated but where it is impossible to find a pleural space

We feel that artificial pneumothorax will often give better results in the acute unilateral cases where there is severe toxæmia and progressive disease and in severe hemorrhages when the bleeding point can be located

On account of its simplicity and having practically *no complication, phrenicectomy* as a teratment for pulmonary tuberculosis is, in our estimation, to be seriously considered in any case needing mechanical rest

Case Reports

Blum—Admitted May 7, 1929 Moderately Advanced, improved symptomatically on rest September 9th hemorrhaged and x-ray and physical showed cavitation Phrenicectomy September 21st At present quiescent with negative sputum and cavity fairly well healed Reason for phrenicectomy apical cavity that probably couldn't be collapsed with pneumo-

Jackson—Admitted September 5, 1929 Temperature 101, hemorrhaging *X*-ray showed cavity increasing in size and increased infiltration at base over picture of Feb 1929 *Pneumothorax was decided as* cavity was central and symptoms acute Results *good*, patient has no active symptoms

Osborn—Admitted Sept 26, 1928 Far Advanced B *X*-ray showed basal lesion right, improved on rest began to hemorrhage March 1929 continued Started pneumothorax April 15th *impossible to collapse cavity, hemorrhage* only partially controlled Died from spread of trouble She had phrenicectomy performed Sept 7, 1929, which controlled hemorrhage We felt that she should have had a phrenicectomy instead of pneumothorax but it was not possible to have it done at that time

Callahan—Admitted Nov 5, 1929 Moderately Advanced, with lesion at right base Disease extended under rest and no symptomatic improvement Phrenicectomy done Jan 8th, with good results

Hershey—Admitted Jan 12, 1928 Advanced Hemorrhaged at intervals Pneumothorax could not be given Phrenicectomy performed March 26 1930 Diaphragm reached its maximum height in 5 days No hemorrhage since operation and 50% decrease in sputum and cough and temperature normal since operation Object of operation was preliminary to thoracoplasty but has improved so much he may not need the thoracoplasty

Dorwalski—Admitted July 8, 1929 5 weeks before entrance hemorrhaged Temperature from 101 to 102 with rales throughout left and infiltration scattered *through left* On account of severe toxæmia pneumothorax was started Aug 17, 1929 with practically no fever or active symptom since Sept 1929

Humphrey—Admitted Feb 6, 1930, had a hemorrhage Jan 17th and 3 since In Dec diagnosed early minimal On entrance post-tussive rales in left upper ⅔ and no improvement in condition on rest for 2 months *X*-ray beginning to show excavation at apex Patient desired phrenicectomy in preference to pneumothorax Operation March 26th, has *improved symptomatically but still runs slight* temperature She may need pneumothorax later

RADIUM IN DERMATOLOGY*

By WILLIAM H. CAMERON, M.D., NEW YORK, N. Y.

From the Department of Dermatology and Syphilology, University and Bellevue Hospital Medical College.

A PROMINENT professor of surgery recently advised his students,—"Forget all you hear about radium." Such an opinion, expressed some twenty-five years after its introduction as a therapeutic agent, makes one wonder if information regarding the use of radium is being properly disseminated.

In attempting to answer this question, I reviewed considerable literature on the subject and was impressed with the following facts: First, it is radium, and not the technic of its application, that is adversely criticized. Second, it is apparent that the most important problem—the question as to whether, from a physiological standpoint, radium should, or should not, have been used—is seldom considered. Third, a technical uncertainty as to whether, in a given case, the beta or gamma rays from radium, or the gamma rays from *x*-ray, were indicated.

As to the first point, the criticism, in a great majority of cases, should be reversed. The fundamental principles of radiation can be taught, but radiological judgment can only come through experience. The second and third points present so many ramifications that it is impossible in the time allotted to discuss other than a few of the general principles involved.

During my early experience, I was fortunate in having the advice and help of that splendid physicist—Charles H. Viol, Ph.D.—and, also, in being able to command amounts of radium ranging from 10 to 1,000 milligrams.

We were finally able to predict, with reasonable assurance, how certain kinds of normal and abnormal tissue should react to various ray doses. We also became aware of the caustic properties of the rays, but we were never able to fathom just how the rays acted on certain tumor cells to bring about a disintegration of the tumor without an apparent destruction of tissue. This latter effect is now described as an autolytic degeneration, but as the mechanism of its production still remains unsolved, part of the subject matter herein discussed is based on empirical evidence.

Bactericidal Property of the Rays: After many tests, we concluded that while the beta rays had some slight effect, the bactericidal action is, for all practical purposes, nil. I have never doubted the correctness of this conclusion, consequently have never used radium with the object of destroying bacteria.

In small fungoid lesions of long standing, the beta rays did seem to have some value. I believe, however, that we must attribute most of this effect to some change produced in the soil, rather than a direct effect on the fungi.

Even when we used large amounts of radium it took so many hours to sterilize tubercular cultures, that efforts in the direction were discontinued. We did, however, try radiation in five advanced cases of pulmonary tuberculosis. These patients received radiation from 500 milligrams (radium was divided into small units and arranged over the chest wall at an equal distance from each other and at a skin distance of 3 cm.) for 72 hours. We noted no change in the clinical aspect or in the number or shape of the bacilli expectorated. As a result of this work, I have not, as a rule, used radium in tuberculous lesions of the skin or mucous membrane.

On the other hand, the clinical results in tubercular adenitis are very good,—that is, of course, when we exclude glands containing caseous material. Here, again, I believe the soil is influenced, and not the infection.

As the rays did not seem to have any effect on the spirochetes, efforts along this line were discontinued. In this connection it must not be forgotten that many mouth cancers, for instance, also give a four plus Wassermann test; therefore, all mouth ulcers of a syphilitic nature that do not show definite improvement under approved antisyphilitic treatment, must be further investigated.

Effect of Radium on General Metabolism: During the experimental work referred to, many observations were made as to the possible systemic effect of the rays. In addition to applying radium locally, we administered, intravenously, doses of the element ranging from 10 to 1,000 micrograms, and, by mouth, gave radon solution in doses up to 5,000,000 mache units.

Many promising clinical trails were followed, often to find at the end of the trail a "why" cloud we could not penetrate. There can be no question, however, that the blood picture is temporarily altered when radium is introduced directly into the blood stream, and, what is more important, the same effect may be produced when the blood stream merely passes through a part of the body being subjected to hard radiation. Later we were to learn that repeated exposure to enormous doses of the rays profoundly and permanently altered the blood picture. From this we learned that patients presenting idiopathis anemias, for instance, must be rayed with the utmost care and that radium operators must, at all times, guard against undo exposure.

That the body chemistry is permanently deranged by radium rays is improbable. The only thing we found in this direction, was a tempo-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

rary increase in the ethereal sulphur content of the urine. We could not see that radium would prove of value in cutaneous lesions that might be caused by some defect in metabolism.

Effect of the Rays on Abnormal Tissue: When reports are mustered, one finds several separate and distinct reactions listed by so many investigators that they should, I believe, be accepted as established facts.

Retardation of Growth: This effect is accomplished in certain new growths, because some of the tissue elements composing the growth are radio-sensitive. In this class of cases, the radiumtherapist, knowing that palliation is all that can be accomplished, will direct his efforts toward this end. If he does not recognize limitations and persists in radiation, considerable harm may be done.

Caustic Effect of the Rays: This effect is too well known to doubt. What many physicians do not seem to realize, however, is the fact that it is possible to deliver a caustic dose to diseased cells without actual destruction of the surrounding healthy tissue.

Cold surgery has no control over diseased cells that might be beyond the line of incision. Hot surgery, while somewhat better in this respect, is also limited in this direction. Other caustic agents have little, if any, effect beyond the point of application, but radium rays, while producing a caustic effect in a given area, will check cell division in a still larger area, and, even beyond this point, they may cause the cells to be encapsulated.

Autolytic Degeneration: As previously stated, this effect, noted in certain neoplastic diseases, has not been explained. Perhaps the rays induce some chemical change in the cell, or possibly there is some control exercised over the nerve supply; the fact remains, however, that we frequently see large lesions disappear with hardly a trace of their having existed.

Tissue Conversion: It is possible, with a well regulated dose, to change slightly the character of tissue, and by so doing, clear up a superimposed pathologic change. Such a procedure is to be recommended only in non-malignant lesions of small area and of long standing.

Radiation Limitations: A reasonable understanding of the ray resistance of normal tissue and the ray response of pathologic tissue, is necessary before one should attempt the extensive use of radium. While our knowledge of this subject is not, by any stretch of the imagination, complete, there is enough to keep one from attempting the impossible.

Using the susceptibility, or the non-susceptibility of the lesion as a basis for a radiation schedule, the following abbreviated list will illustrate the point I wish to make:

Benign Lesions

Keloids. If this condition is of recent development, it should be very sensitive to the rays, and may be controlled with a rather light but homogeneous dose. Cases of long standing should, first, have a trial ray dose and if there is no response in a reasonable time, additional radiation should not be given.

Flat surface Angiomas: Because the rays will produce an endarteritis in the superficial vessels, beta rays, when carefully applied, are of considerable value.

Planter Warts: These lesions are responsive, and if small in size, they are rayed. When large, I prefer to remove the wart and ray its site.

Pre-Cancerous Lesion

Elevated Pigmented Moles: A pigmented mole that is, or may become, subjected to more or less constant friction, should be removed. They are not, strictly speaking, radio-sensitive. The elevated portion will dry up and drop off with a rather light dose, but it requires a full caustic dose to remove pigment deposited in the skin. Because of the severe reaction that will follow this practice, radiation is not justifiable, especially when the entire lesion may easily be removed by fulguration.

If malignancy is suspected, the cells should be devitalized by a full caustic dose. Five or six days later, the radiated area should be removed by fulguration and the tissue carefully examined. If melanotic invasion is positive, a wide circle of tissue surrounding the seat of the mole should be rayed with deep radiation to the draining lymphatic areas.

When the clinical evidence of malignancy is beyond question, these lesions should be widely and fully rayed. I do not mean to imply that this procedure will control the situation. As a matter of fact nothing that I have ever used will control a case in which the blood stream is the carrier. On the other hand, it is just as liable to be a case wherein the extension is a lymphatic problem, and, here, considerable palliation can be had by rational radiation.

Leucoplakia: These lesions are not very radio-sensitive, and, as the base of the lesion must be brought under control, gamma rays are indicated. The dose should be hard enough to almost equal that intended for complete caustic destruction. For this reason, small patches should be removed by fulguration. Cases presenting the slightest malignant invasion are treated as squamous-cell epitheliomas.

Benign Tumors

Fibromas, Chondromas, Osteomas, Lipomas: Because their predominating tissue is not radio-sensitive, these connective tissue tumors are not rayed.

Myxomas, Angiomas, Lymphomas: This group

of connective tissue tumors are very sensitive and may be controlled with an autolytic dose.

Simple Benign Tumors of Epithelium, Muscle and Nerve Tissue: With a few exceptions, these tumors are not responsive and, unless they become vascular or cellular, they are not treated by radiation.

Endotheliomas: Unchanged solid tumors of this type are not rayed.

Tumors of Complex Tissue

Embryomas, Teratomas: Simple mixed tumors of complex tissue are, as a rule, very sensitive to the rays. They are treated with an autolytic dose.

Rational Treatment of Benign Tumors: The rational treatment of myxomas, angiomas, lymphomas, embryomas and teratomas would seem to be by radiation. All other simple benign tumors should be removed but, when on section they are found to contain small round or spindle-cells, the site of the tumor should, I believe, be rayed. When giant-cells are found, radiation is not necessary.

Basal-Cell Epitheliomas: When these embryonic lesions invade the skin, they can usually be cured by any method that will destroy the entire growth. They are very sensitive to the rays, and, because radium will destroy these growths with the least amount of destruction to the surrounding tissue, it is the agent of choice. If the periosteum or cartilage is involved, one should consider fulguration after the radiation.

General Consideration of Carcinoma: When glandular tissue in atypical arrangement is encountered, no matter what line of treatment is followed, one's judgment is, at present, apt to be questioned. Personally I feel that "up-to-date" radiation has a distinct place in the treatment of all such cases. Having had three years' experience with a two-gram radium element pack,** I am more determined than ever on this point and do not hesitate to recommend radiation before and after operation, even when operation seems to be clearly indicated. I am also of the opinion that adequate radiation of the draining lymphatics is of distinct value.

The question of what cases to ray and what cases to operate, can only be decided after careful consideration of the individual case. Likewise the radiation technic is an individual proposition. In general, lesions growing rapidly, having young blood-vessels and containing many cells, should be rayed.

** The radium pack mentioned consists of twenty-one hundred milligram radium element tubes. These tubes are arranged in a circular disk the diameter of which is 8 cm. The silver tubes are permanently locked in position. Surrounding the radium (three surfaces) there is a lead shield 14.8 cm. On the treatment surface the shield is 6 cm. The center of this surface is drilled (diameter 9 cm.) to give free passage to the gamma rays. With this instrument we frequently give from 14,000 to 50,000 mgm. hrs. through a skin area. The distance is from 6 to 15 cm. To the pelvic and abdominal regions the total radiation (three, four or five skin areas) may run up to 200,000 mgm. hrs.

Epidermoid Carcinoma: After raying a number of lesions of this character, I noticed that cases, apparently presenting the same clinical picture and what was thought to be the same cell arrangement, did not respond in like manner, to the same ray dose. All cases were given a caustic dose but to what extent this effect should be carried was, and still is, a difficult question.

Broder's work would seem to explain many of our difficulties in this direction and, also, explain the wide variation in reported results.

Using Broder's classification of cell types as a treatment guide: In types one and two, good surgery or thorough radiation, used early enough, should give good results. Cases falling under types one and two must be thoroughly rayed with a full caustic dose. In many of these cases the patient should have a voice in the matter.

In types three and four, radiation has a distinct advantage even in early cases, for it is the most malignant types that are the most responsive to the rays.

The Doubtful Tumor: Frequently tumors cannot be diagnosed, and, if not advisable to perform a biopsy, a trial ray dose is suggested. If the tumor responds, one is justified in giving additional radiation as being, perhaps, the best form of treatment to use. If there is no response, it is folly to push radiation. If the tumor cannot be removed, some palliation is had by such a procedure. If, on the other hand, the tumor can be removed, radiation has helped rather than hindered the operator;—that is, of course, if the dose has been rational and the operation not too long delayed.

Where to Use Primary Beta Rays: Being rapidly absorbed by soft tissue (1.0 mm. absorbs 50%; 2.0 mm., 75%, etc., etc.) primary beta rays have very little therapeutic value in lesions where the base is more than five millimeters from the point-source of radiation. By partial screening (using metallic screens of varying thicknesses to absorb a portion of the soft beta rays) and by increasing the time of application, this area may be somewhat increased.

It must be remembered, in this connection, that the ratio of soft rays to the total beta ray output, is an unknown factor; that the soft beta output differs widely in applicators of the same strength; that skin reactions are fluctuating, and, by any devise, that it is impossible to force the beta rays beyond a certain point.

It is obvious that a universal beta ray technic is unsound. In my opinion their use should be restricted to the treatment of very superficial non-malignant skin lesions, and sound judgment in their use cannot be exercised unless the operator knows the miximum time it takes his particular applicator to produce a reaction, with the full beta ray output, that is well within an excoriating erythema.

When to Use Gamma Rays: Although it has not been demonstrated, microscopically, I have always felt that the gamma rays spontaneously produced by radium had a different effect on tissue from that produced by the gamma rays from *x*-ray. Watching the reactions produced by a two-gram radium element pack, has served to increase this impression, but, be this as it may, *when a radio-sensitive lesion requires a concentrated and penetrating ray dose, or, when a caustic effect must be secured, use radium.*

Conclusion

In reviewing the literature and in verbal discussions, one is confronted with many conflicting statements regarding the therapeutic value of radium. This is, to say the least, confusing, especially for one seeking specific information, and, under the circumstances, much of the adverse criticism is justifiable.

Most physicians think of radium as being a single agent, when, as a matter of fact, it is only a means of generating rays,—rays that are capable of being manipulated in such manner *that it makes radium, not one, but at least four,* separate and distinct agents. It is only when one considers the subject from this standpoint that the true value of radium may be appraised, and, finally, while the art of ray manipulation consists in a knowledge of their physical properties, the true art, in radium work, consists in a knowledge of pathologic conditions and their ray response.

DIAGNOSIS OF BILIARY TRACT DISEASES IN THE EARLY STAGES*

By JOHN A. LICHTY, M.D., F.A.C.P., and SARAH BOWEN, M. D., CLIFTON SPRINGS, N. Y.

THREE years ago at the meeting of this Society at Niagara Falls, a paper was presented by Dr. Chas. W. Webb and myself, (J. A. L.), entitled "The Cooperation Between the Internist and the Surgeon in Handling Biliary Tract Diseases." That paper dealt almost entirely with the surgical aspects of the diseases occurring in the biliary tract. It was recognized that there is a time when biliary tract diseases become definitely surgical, and it was agreed that at such a time it is highly desirable that the surgeon and the internist cooperate in so far as the course to be pursued is concerned. Such cooperation should cover the possible operative risk, as well as the pre-operative and post-operative care. The paper did not especially cover the early manifestations of the various diseases of the biliary tract, neither was it suggested that a certain early medical treatment might be indicated and carried out to the advantage of the patient. It was conceded, however, that —"Certain disturbances of the gall bladder and ducts may be of such a nature that the mechanical interference which surgery implies, may not be necessary." This position was taken with the full knowledge that there are those clinicians who contend that biliary tract disease is always surgical, or will sooner or later become so.

It is the purpose of this paper to present an analysis of the same group of patients from which the data of the former paper were obtained, with the idea of determining whether an earlier diagnosis, at least tentative, might be made which would lead to a persistent rational medical and dietetic treatment. This investigation is thought desirable, because of the fact that there is still a considerable surgical mortality, and also because there is an impression, especially on the part of certain surgeons, that there is a certain inexcusable delay on the part of the internist in recognizing the early symptoms of biliary tract disease, and in instituting desirable treatment and care. The patients are encouraged to delay until surgery is done at a considerable risk.

The classification, or grouping of biliary tract diseases in this study is not based so much upon the pathology likely to occur in the right upper quadrant, as it is upon certain signs and symptoms significant of biliary tract dysfunction.

This distinction is made because the early symptoms and signs of certain biliary tract diseases may be quite meager and apparently insignificant, and yet common to a number of possible conditions.

In reviewing the diagnoses made during the past ten years in the Clinic of the Clifton Springs Sanitarium, the following grouping of cases occurred:

TABLE 1

BILIARY TRACT PATIENTS—1920-1929, INCLUSIVE.

1. Diagnoses verified by operation or autopsy		218
1. Chronic Cholecystitis	117	
2. Gall Stones	59	
3. Pericystic Adhesions	28	
4. Carcinoma	11	
5. Empyema	3	
2. Diagnoses not verified		375
1. Acute Cholecystitis		
2. Chronic cholecystitis with acute exacerbations		
3. Chronic cholecystitis		
Total		593

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

It will be seen that 593 patients have been included in this study. It will also be seen that in 218, the diagnosis was verified by operation or autopsy. These no longer concern us in this discussion excepting in the lessons they teach.

It is the 375 patients in whom the diagnosis has not been absolutely verified that demand our attention. In many of these a more definite tentative diagnosis has been made, such as, catarrhal jaundice, angiocholitis, certain specific infections, cholelithiasis and certain other conditions obstructing the biliary tract, but in many more, a wholesome diagnostic reservation was necessarily maintained.

It seems to be generally accepted that repeated attacks of catarrhal jaundice are the result of a mild cholecystitis; that an acute cholecystitis may by recurrences develop into a chronic cholecystitis; and from this may develop gall stones, pancreatic disease, and later, malignancy. If such a sequence is possible, it would seem reasonable, the earlier it is recognized the more likely it could be interrupted by such therapeutic measures as are indicated. It is perhaps unfortunate that the narration of certain supposedly early symptoms, such as "fair, fat, forty, with excessive flatus" is almost invariably the occasion for levity among physicians, or for anything but serious thought, whereas these may be the very first signs of beginning biliary tract disease.

TABLE 2

1. *History:*		
1. Age (average)		52¼
2. Sex—Male 153—Female 440		593
3. Pregnancies		200
4. Previous Infections—(Typhoid, etc.)		62
5. Metabolic Disturbances		
(a) Obesity		
Ht. and wt. recorded		433
(a) Normal	133	
(b) Underwt.	161	
(c) Overwt.	139	
(b) Glycosuria		41
—2. *Symptoms:*		
1. Flatulency		238
2. Constipation		246
3. Jaundice		150
4. Localized Pain		293

In the analysis of our cases we were not impressed so much with the complexion—that is, the distinctive blonde—as we were by the tendency to obesity. The well-nourished, obese type, with gormandizing tendencies, is likely to reveal symptoms of biliary tract disturbance. The same individual not infrequently shows disturbance of carbohydrate metabolism as evidenced by an occasional glycosuria.

Flatulency was an outstanding symptom in 238 of our cases. When complained of, it should receive more than ordinary consideration. In the analysis of this symptom it should be determined whether the gas is due to digesive disturbances, or only to the swallowing of air. Swallowed air contains a large proportion of nitrogen which is not absorbed in the stomach as oxygen is, and therefore may produce greater discomfort than gas due to fermentative action.

Biliary tract disease in its early stages seems to be associated with a hyperchlorhydria, and in the later, or chronic stages, with a hypo-, or achlorhydria. Either or both of these conditions may be responsible for the persistent flatulency experienced by some of these patients.

Careful investigation of gastric secretion may reveal the earliest evidence of digestive disturbance, and may also help in establishing a rational treatment.

Constipation was noted in 246 of the cases. While it is not so distressing a symptom as flatulency, it causes considerable concern to the patient. It usually receives scant consideration from the doctor. Between the two a great deal of harm may be done by the unfortunate selection of cathartics. Continued neglect thus may aggravate a condition which, with proper care, might have been easily overcome.

Jaundice was reported, or seen 150 times, and bile was noted in the urine 37 times. There was an increased icteric index found in the blood a number of times. Frequently these disturbances were of only a slight degree, yet they pointed definitely to the fact that something had happened in the biliary mechanism which required interpretation.

Localized pain and tenderness were of the greatest concern to the patient. It was noted in 293 patients. The peculiar radiation of the pain followed the classic lines in some cases, that is, along the right costal margin and to the right scapulae. In other cases, however, the radiations were quite bizarre, such as to the precordia, to the neck and shoulders, and occasonally down the arms. It was very helpful to keep close watch of the temperature, blood and urine during the occurrence of the attack. It is our firm impression that if these four, rather minor symptoms, flatulency, constipation, jaundice and pain in the right upper quadrant, with increased temperature and a leucocytosis, even of the slightest degree, were considered more carefully, and if a line of symptomatic treatments were instituted, even

though the diagnosis is still in doubt, many of the serious complications in biliary tract disease might be avoided.

TABLE 3

Laboratory Aids:		
1. Bile in urine		37
2. Blood Serum (Icteric Index)		
(a) (4- 10 units)	32	74
(b) (11-200 ")	42	
3. Leucocyte Disturbances:		215
(a) Leucocytosis	162	
(b) Leucopenia	53	
4. Gastric Secretion Studies:		287
(a) Normal	115	
(b) Hyperchlorhydria (early)	119	
(c) Hypo-& achlorhydria (late)	53	
5. Duodenal Aspiration ("Lyons Test")		120
(a) Normal	51	
(b) Path.	69	
6. Roentgenological Examinations:		566
(a) Gastro-intestinal Series	307	
(b) Cholecystographic	259	

While such a tentative treatment is followed out, certain well-established laboratory procedures should be systematically followed which might lead to a more definite diagnosis. To some of these reference has already been made. These are, the examination of the urine, not only for bile, but also for sugar; the study of the blood, not only for leucocyte reactions, but also for pigment in the serum and for change of sugar content.

Duodenal Aspiration, or drainage, according to Lyons' method, was done, but not routinely. At times it gave definite diagnostic confirmation and again the results were disappointing. It is probably more helpful as a therapeutic measure than as a diagnostic one. It is scarcely necessary to call attention to the fact that laboratory tests in these studies, to be of any value, must be repeated many times.

The advantage of careful *x*-ray examination in suspected biliary tract disease depends largely upon the care taken in interpreting the films. A complete gastro-intestinal series may at once give positive evidence of pathology in or about the biliary tract. On the other hand, the findings may be only indirect, such as an abnormal fixation of the duodenum, or the hepatic flexure, or a gastro duodenal hyperperistalsis. Cholecystography in recent years introduced by Graham of St. Louis, is destined to become of great diagnostic value. At present its originator is hopeful that it may also prove of surgical prognostic value, in that it may reveal the functional disturbances of the liver and determine the degree of surgical risk, and surgical safety.

Gastro-intestinal studies were done in 307 patients of our series and cholecystography examinations 259 times. These latter were done only in the past five or six year. With our present experience we conclude that *x*-ray examinations in the study of biliary tract lesions give positive information only in the later stages of the disease. Its greatest value is probably in determining whether a given case has become surgical, and it appears, therefore, from our present experience, of little value in establishing an early positive diagnosis. It is helpful in differentiating from other more advanced lesions or conditions.

The application of the plan suggested in this study is easily illustrated by the following case report:

Mrs. M. G., age 53, housewife, entered the Clinic, June 9, 1929, complaining of obstinate constipation, of sudden, and unexpected attacks of dizziness, nervousness and weakness, These symptoms began in about the order named, five years ago, and seemed to be gradually getting worse. Associated with these symptoms were gas in the abdomen, manifested by distension and a peculiar churning sensation which came sometimes immediately after meals and at other times two hours or so after the meals. There was occasional pain in the upper abdomen but never to the degree of requiring hypodermics of morphine. The patient had a peculiarly keen appetite, described sometimes as a craving, gnawing sensation in the upper abdomen. She also had frequent headaches and seemed to have developed a state of chronic invalidism. There was no history of urinary disturbance. She had never been pregnant. No history of any acute infectious diseases. Twelve years ago had "low back pain" for which a laparotomy was done for a so-called prolapse of the uterus. From this she made a good recovery but the back pain remained the same.

At the time of admission patient was about 20 pounds below her usual weight and had a sallow complexion. Pulse rate was 64, regular, and blood pressure 112/60. No evidence of cardiac disease. The lungs were normal. There was no tenderness in the abdomen; no organs or masses palpable. Pelvic examination was negative. Laboratory examinations were as follows: Urine 1016, acid, no albumin, sugar, bile or casts.

Blood—Haemoglobin	65%	
R.B.C.	3,250,000	
W.B.C.	5,400	
Neutrophiles		42%
Large Lymphocytes		17%
Small Lymphocytes		35%
Eosinophiles		4%
Myelocytes		2%

slight poikilocytosis, a few macrocytes and microcytes.
Complement fixation for lues—negative.

Blood chemistry:

Icteric Index	16,
Vanden Bergh	(direct) Questionable at 30 mins.
Fouchet	Questionable
Sugar content	0.097

Gastric Analysis—fractional

Residue	19—35
30 mins.	24—38
45 mins.	28—54
60 mins.	48—78
1 hr 15 mins.	61—94
1 hr. 45 mins.	56—78
2 hrs. 15 mins.	42—58

Duodenal aspiration showed the so-called "A, B. & C." bile with mucus. It seemed to afford relief of symptoms.
Phthalein test 50% in two hours.
Gastro-intestinal series gave evidence of adhesions in the right lower quadrant and also of spasticity especially in the descending colon. Stomach was normal.
Barium Enema: The colon appeared to be freely movable. There were no areas of obstruction. Ileo caecal valve was incompetent. There was no pain during the examination.
Cholecystography: No evidence of gall stones. The shadow of the gall bladder appeared normal in size, shape and position in 15 hours. In 20 hours the shadow was about gone, suggesting a normally functioning gall bladder.
X-ray of the chest revealed the markings of an old healed lesion opposite the left hilum.
The test of the ears showed normally reacting auditory and vestibular function in both ears.

It was concluded after these examinations that there was present a spastic condition of the colon, a hyperchlorhydria, probably of long standing, and a certain biliary tract disturbance as evidenced by the changes in the blood serum, suggested by the increased icteric index.

A course of treatment suitable for such a condition was established and at the end of three months the patient felt much better, had gained 20 pounds in weight, and had more natural bowel movements.

The patient was advised to follow her regime as closely as possible at home.

Follow-up letters have shown that she continued to improve, and in her last letter of a month ago she states—"I am much better in every way."

It is not the purpose of this paper to discuss the treatment of such conditions as herein considered. The case reported is illustrative of the studies which may be made and results possible in a certain proportion of patients presenting the conditions described. The inference is that the earlier these conditions are recognized, the more likely the results will be satisfactory. Also the conclusion follows, in conjunction with Dr. Webb's paper, to which reference has been made, that the sooner the failure of medical treatment is demonstrated and the safety of operative treatment is established (other things being equal), the lower the surgical mortality will be.

Discussion by Dr. E. C. Reifenstein.—Internists will agree with Dr. Lichty that the problem of the diagnosis of Biliary Tract disease in its early stages is important and that an attempt should be made to establish the diagnosis, or at least make such a diagnosis tentatively. I agree with him as to the relative significance of these symptoms and signs and simply wish to emphasize the importance of the apparent mildness of the complaints. In fact these symptoms and signs are often so mild as to be entirely ignored. Often the laboratory evidence is disappointing. The most significant laboratory findings are: The transitory glycosuria and the occasional presence of bile and urobilin in the urine. The evidence from the Roentgen Ray frequently fails to give additional helpful information; however, there are times when the indirect signs, as has been mentioned, will be of considerable value, particularly the presence of a spastic colon. Whenever a spastic colon is reported by the Roentgen Ray examination it is important to consider dysfunction of the gall bladder as one of the possible associated conditions.

While pathology was not discussed it is important to direct attention to the fact that circulatory disease with stasis of the liver may be associated with the same symptomatology as Biliary Tract disease. It is clinical experience that Coronary artery disease associated with myocardial failure frequently presents symptoms and signs referable to the upper abdomen.

I agree with Dr. Lichty that if careful attention is given to diagnosis and treatment of Biliary Tract disease in the early stages, much may be accomplished by treatment and possibly serious damage to the liver and gall bladder prevented.

STERILITY SECONDARY TO INDUCED ABORTION WITH SPECIAL REFERENCE TO THE TUBAL FACTOR*

By I. C. RUBIN, M.D., F.A.C.S., NEW YORK, N. Y.

THE frequency of abortions has been the subject of discussion for a long time. Taussig[1] in 1910 estimated the incidence of abortions to be 25% of all pregnancies. Royston[2] in 1917 estimated it at 23.8% and De Lee[3] states that almost half of all child-bearing women have had an abortion before the thirty-fifth year. The majority of the abortions have been induced, according to some authors.

Opinions differ as to the pernicious effect of artificial abortions upon later pregnancies and labors. According to Jacob[4] 50:60% of all gynecological patients date the onset of their illness from an abortion. Klein[5] on the basis of 1,531 cases concludes that many pathologic pelvic lesions are referable to previously induced artificial abortions. Vogel[6] and Atzerodt[7] independently claim no such deleterious results. This difference in conclusions is perhaps due to the inequality of their control cases. For example Atzerodt compares 184 labors following abortion with a series of 3,964 labors without an antecedent abortion. Study of an equal number of labors subsequent to artificial abortion might show a greater percentage of complications.

The comparison made by Klein[5] in this respect is fairer because he compares 593 patients who had had induced abortions to 938 who had not been artificially aborted. Klein's conclusions are confirmed by De Lee,[3] Serdukoff,[8] Broninkowa,[9] and others.

The present study of sterility secondary to induced abortion comprises 219 cases. There are, however, in the same series from which these have been taken, 239 cases of spontaneous abortions preceding the relative sterility and 225 cases of one or two children sterility with which they may be compared. These groups are close enough in number to bear comparison.

In spite of the prevalence of voluntary sterility secured by contraception and artificial abortions it is not uncommon to be consulted by patients for relief from an acquired sterility. Of a personal series of 2,557 cases of sterility 9.3% gave a history of spontaneous miscarriages and 8.6% of one or more induced abortions.

It is not always possible to ascertain the exact number of cases in which an abortion has been induced and by what method, except in a class of patients who feel that it is probably best to tell the truth about the abortion in order to improve their chances for successful conception and pregnancy to term. Estimates of artificial abortion as a cause of sterility vary considerably. Royston[2] has felt that 60% of all induced abortions result in more or less permanent sterility. This may have been true for one particular series and will not hold for another. In this connection the Russian publications on the subject have special value.

The general impression of the deleterious results of an operation which has been notoriously fraught with dangers and complications has gradually become replaced by definite statements based upon fairly large series of cases as those to be quoted. Since studies in sterility have been taking more precise account of definite factors which make for permanent sterility, the earlier figures will naturally undergo further revision. The present study deals more especially with one factor, namely the condition of the fallopian tubes which is now amenable to precise diagnostic determination. By a comparative study of etiological factors it may be possible in this one respect at least to establish the site of the lesion.

The last decade has seen the astounding inauguration of legalized abortion in Soviet Russia. There is thus afforded an opportunity of seeing the effect upon women who have had one or more artificial abortions where the clandestine element plays no role in contributing towards pernicious effects. A well balanced report is available by Serdukoff.[8]

Serdukoff[8] discusses the effects of artificial abortion upon the female organism from various points of view based upon observations of seven years during which time artificial abortion for social reasons was legalized in Russia. The number of abortions in Moscow for example increased from 7,969 in 1922 to 31,986 in 1926. The births had increased in the same period from 35,320 to 57,537. Comparison of the labors and puerperia in 1,723 cases without abortion and 661 cases with two, three and four abortions in Serdukoff's[8] report showed the following:

1. Febrile puerperium was 3 times more frequent in patients who had had previous abortions than in those who had no such interference.
2. Duration of labor was 3 times as long.
3. Low placental implantations 3½ times as frequent.
4. Placental tears and pathological changes 2½ times as frequent.
5. Subinvolution 4 times as frequent.
6. Inflammatory sequelae more frequent. A considerable percentage of chronic gynecological affections owe their etiology to artificial abortion.
7. The foetus was more often dead and macerated.

Serdukoff[8] is convinced that the premature destruction of the corpus luteum and placenta entailed by the artificial abortion causes a deprivation of endocrine function which manifests itself frequently in uterine atrophy and shrinkage to

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

infantile proportions. In the cases of atrophic uteri following abortion tubal insufflation showed the tubes to be open. The trauma of artificial abortion manifested itself in permanent sterility following artificial abortion in young women during the early periods of gestation. In a large number the menstrual function was altered resulting in oligomenorrhoea and amenorrhoea. Serdukoff[8] speaks of determining the permeability of the tubes in the cases of secondary sterility due to artificial abortions as part of the diagnosis and treatment but does not give his results.

Incomplete abortions in Russia are becoming less and less frequent according to Serdukoff.[8] The effect of artificial abortion in young women of 17 to 18 years is especially noteworthy. He blames the abortion even where no inflammation has set in for "provoking an irremediable sterility."

From another Russian clinic Kallinekoff[10] reports 1,000 abortions performed in two years; in only 5% a medical indication for the termination of pregnancy was present. These 1,000 women had from 1 to 11 artificial abortions and the author believes that a properly performed abortion produces no subsequent disturbances. He adds however that some women have spontaneous miscarriages after a series of artificial abortions.

The incidence of fever is appreciable even where the operation of artificial abortion is done under favorable auspices. Thus Levit[11] reports that among 780 women who entered the hospital for legalized abortion and were without fever and were curetted, 13% had a single elevation of temperature; 6% had such an elevation twice; 5% three times and 20% four times. He states that these mild infections after curettement are frequently the cause of serious sequelae, such as extra-uterine pregnancy and sterility. Levit[11] states that in a series of 2,930 artificial abortions performed from 1913 to 1926, the curettement was followed by chronic affections of the genitalia in about 20%.

In any statistical investigation bearing on the question of abortions it will probably always be difficult to determine how many of the supposed spontaneous miscarriages were actually miscarriages. That applies equally to the so-called induced abortions because an interference may have taken place in the presence of a functional amenorrhoea, no gravidity actually being present. The performance of a curettage in such cases appears to have some etiological bearing on the subsequent inability to conceive. If the material escaping from the female genital tract after a delayed period and the curetted material could always be subjected to laboratory examination as advocated by Huntington[12] our statistics would obviously be of far greater value.

In this present study, women who have had several children and also artificial abortions are not included. I have also excluded those women who have never chosen to become mothers repeating the "abortion" as often as they believe themselves pregnant.

It will not be possible in the brief time allotted for this paper to go into a comparative analysis between these groups in all details. The study is therefore limited chiefly to the tubal factor. It is particularly chosen as being the more readily determined and with a degree of accuracy not shared by other lesions of the genitalia.

Gynecological lesions recorded in the 219 cases with a history of induced abortions as ascertained by palpation were:*

1. Diseased adnexa in 97 cases.
2. Fibroids in 9 cases.
3. Retroversion in 40 cases.
4. Endocervicitis in 88 cases.

The diagnosis of "diseased adnexa" was applied to those instances in which the adnexa were found to be enlarged (thickened), or tender or both, whether on one or both sides. The lesions listed above were as a rule combined, especially 1 and 4. The cases of endocervicitis were treated for varying lengths of time till the discharge cleared up. In no instance was insufflation of the uterus done till all signs of tenderness had disappeared.

The retroversion group enter here only in so far as the uterus may have been bent backward by adhesions which resulted as a sequel of the artificial abortion through pelvic peritonitis and perimetritis. It often forms a special etiological factor and shall not be further entered into here. The retroversions were naturally divided into those which did or did not yield to efforts at reposition. The cases with fibroids were possibly erroneously diagnosticated as such in two or more instances because adherent tubes which are closely attached to the uterine walls may simulate fibroid nodules. On the other hand the fibroids could have existed apart from chronically diseased tubes and ovaries, the latter being palpated separately.

Of the 219 cases of induced abortions:

155 patients stated they had had one induced abortion.
31 patients stated they had had two induced abortions.
16 patients stated they had had three induced abortions.
17 patients stated they had had four or more induced abortions.

In the group with one induced abortion economic and social conditions becoming more favorable, the patients later found to their chagrin that they were unable to conceive. The groups

* A comparison between the gross lesions recorded in the cases of secondary sterilities following spontaneous abortion and of the cases of one child sterility would be interesting but has not been undertaken in this present study.

with more than one induced abortion may be said to have included cases where an interference was suffered in the presence of some functional amenorrhoea not due to pregnancy. Some of these patients did not wait longer than a week beyond their regular menstrual period before undergoing an artificial abortion.

It was possible to ascertain the method employed in the induction of abortion in 178 cases, in 41 cases the patient did not remember or could not give definite information.

In 155 cases with the history of one abortion
Curettage was the method employed in 104 cases
Medication was the method employed in 6 cases
Catheter was the method employed in 5 cases
Not stated—40 cases.

In the 31 cases with the history of 2 abortions
Curettage was the method employed in 24 cases
Medication was the method employed in 4 cases
Catheter was the method employed in 2 cases.
Not stated—1 case.

In the 16 cases with the history of 3 abortions
Curettage was the method employed in 12 cases
Medication was the method employed in 2 cases
Catheter was the method employed in 2 cases

In the 17 cases with 4 or more abortions
Curettage was the method employed in 12 cases
Medication was the method employed in 3 cases
Catheter was the method employed in 2 cases

Summary of the 219 cases:
Curettage was the method employed in 152 cases
Medication was the method employed in 15 cases
Catheter was the method employed in 11 cases
Not stated—41 cases.

In 19 cases a definite history of fever and an enforced stay in bed for a week or several weeks was recorded.

In 6 cases the stay in bed with fever was 1 week's duration.
In 6 cases the stay in bed with fever was 2 weeks' duration.
In 2 cases the stay in bed with fever was 3 weeks' duration.
In 1 case the stay in bed with fever was 4 weeks' duration.
In 1 case the stay in bed with fever was 8 weeks' duration.
In 2 cases the stay in bed with fever was 12 weeks' duration.
In 1 case the stay in bed with fever was 6 months' duration.

The abortion was found to have been performed after marriage in 181 cases. In 20 cases no statement was recorded. Eighteen patients admitted having had interference before marriage and in 10 of the latter the abortion anteceded marriage, from 2 to 12 years:

4 cases 2 years before marriage.
3 cases 3 years before marriage.
2 cases 10 years before marriage.
1 case 12 years before marriage.

Inasmuch as we are here concerned with the tubal factor in the sterility following artificial induction of abortion (not done for therapeutic purposes) it is well first to have an idea of the incidence of tubal closure or stricture in the general statistics of sterile patients in whom the matter of tubal patency has been determined by uterotubal insufflation. Thus of 2,338 cases of sterility *not including cases with an induced abortion*, the tubes were tested for patency in 1,746 cases and not tested in 592 because of various contraindications.

The percentage of closed tubes in the primary group of sterilities was 40%. In a series of 650 cases studied with the aid of the kymograph[18] approximately 30% had shown non-patent tubes. Of 239 cases with a history of one child sterility, including a few who had borne two children the tubes were examined in 195 cases and not tested for patency in 30 cases. They were found open 150 times and closed 45 times, giving a percentage of closed tubes of approximately 23%. 201 cases with a history of one miscarriage were tested for tubal patency out of a total of 239 cases. The tubes were found to be open 164 times and closed 37 times, or a percentage of closed tubes of 18.5%.

Analyzing the 219 cases of artificially induced abortions there were 165 cases in which the tubes were tested for patency. Of these 165 cases the tubes were found open 65 times, closed 92 times and strictured 8 times; in other words the incidence of closed tubes in proportion to open tubes was 1.4 times greater. If we add the 8 strictured tubes the percentage may justly be estimated as higher.

Of 19 cases with a history of fever 10 cases proved to have closed tubes and 5 open tubes.

The open tube cases were given a single uterotubal insufflation. The cases in which the tubes were found to be obstructed at the first insufflation were examined again at least once or twice more, except in instances where the tubes had been tested by others and were found to be nonpatent. Fifty-eight of the 92 patients who had obstructed fallopian tubes were personally examined for patency two or more times.

Repeated Artificial Abortion in Relation to Closed and Open Tubes.—In general, repeated abortions tended to increase the probability of finding closed tubes. Thus of 138 cases in which one abortion was performed 55 showed open tubes and 63 closed tubes. On the other hand of 23 cases with a history of 2 abortions 8 showed open tubes and 15 had closed tubes. However in 2 parallel groups of 12 patients with a history of 3 and 4 or more abortions respectively the one

with 3 abortions showed 4 open tubes and 8 closed tubes while the other with 4 or more abortions showed 6 open and 6 closed tubes. To these bare figures must naturally be added other factors such as fever, method employed, etc., which must affect tubal function. The fact must not be omitted that some patients may be fortunate enough to escape infection in spite of the most unfavorable circumstances.

The Relation Between the Method Employed in the Abortion and the Finding of Closed or Open Tubes.—In my series of 103 cases in which curettage was stated as the method employed in the artificial abortion, 46 were found to have open tubes and 57 were found to have closed tubes. Of 10 cases in which some form of medication was used, the tubes were found open 3 times and closed 7 times. Of 11 cases where the catheter was used 4 were found with open tubes and 7 with closed tubes. In 41 cases the method of inducing the abortion was not recorded; of these 20 showed open tubes and 21 closed tubes.

It is obviously difficult to imagine how medication taken orally would cause blockade of the tubes except by its toxic effect upon the ovum and by inciting violent uterine contractions. These may be responsible for retrograde transportation of blood and mucous particles from uterus to tubes.

The anatomical site of tubal closure is of great interest from the point of view of possible therapy and prognosis. A comparison in the special incidence of this fact between the group of spontaneous abortions and artificial abortions including different methods employed in performing the abortion would be of great scientific interest. My records appear to suggest that the uterine end and the isthmus bear the brunt of the infection in those patients who were artificially aborted. This is in marked contrast to the site of the tubal closure, namely at the fimbria, following Neisserian infection.

It is realized that these findings may be modified somewhat by a larger number of cases. The matter of coincidence must apply particularly to the smaller groups herein presented. But the study so far points to the overwhelmingly greater preponderance of permanent sterility due to tubal occlusion following artificial abortion. The reasons for this are not far to seek. 1. Poor or imperfect surgical asepsis. 2. Lack of skill in performing the abortion in many cases. 3. The failure to stay in bed for a proper period and the ambulatory fashion in which the patient is expedited from office to house or business. Finally, 4, the element of concealment. All these conspire to induce pathological changes in the female genitalia.

The fallopian tubes are extremely susceptible of irreparable damage. The latter is favored by the frequency of retained products of conception which results from incomplete operations, the production of true post-abortive endometritis; direct ascending infection of the tubal mucosa; the sealing over of the tubes by peritubal adhesions resulting from lymphatic extension of the infection of the serosa of the pelvic organs.

The comparatively small incidence of closed tubes (the smallest incidence of all the groups) obtaining in the cases of secondary sterility with spontaneous miscarriage points to the importance of not resorting to curettage unless the exigency of excessive bleeding demands it. The present study strengthens the position of those who advocate non-interference in spontaneous miscarriages, certainly from the viewpoint of the future fertility of the patient.

Of the 219 cases of artificial abortion 18 became pregnant following utero-tubal insufflation. (These 18 patients gave a history of 26 induced abortions before coming for treatment.) Of the 239 cases of spontaneous abortions, 31 became pregnant following utero-tubal insufflation. (These 31 patients gave a history of 38 spontaneous miscarriages.) Insufflation was the only treatment given these patients. A therapeutic effect can best be considered in the cases with strictured tubes. Thus of 205 pregnancies following utero-tubal insufflation 42 yielded to repeated perflation of the tubes where strictures of varying degrees had existed.[14]

Operative intervention holds out some hope in a certain percentage of cases with sealed tubes. Kerwin's recent report[15] is encouraging. There is no doubt that with more painstaking efforts, with advances in our knowledge of tubal function and pathology, and improved operative technic some of the groups of otherwise hopelessly sterile women who are rendered sterile by sealed tubes may be restored to fertility. The operation of salpingolysis, of tubal implantation and of ovaro-uterine implantation will be resorted to more frequently in the future. Adjuvant measures such as rest, hydrotherapy, protein therapy, diathermy are agents which can be useful in the cases of less prolonged duration with evidences of recent inflammation. Utero-tubal insufflation has been demonstrated to exert a therapeutic effect on the cases with incomplete strictures of the tubes. The occasional pregnancy which appears to follow the injection of lipiodol suggests its therapeutic use as well as diagnostic value. These are measures that will have to be depended upon so long as no specific methods are yet available to cause the permanent disappearance of peritubal adhesions and of intratubal agglutinations.

Conclusions

Sterility which is anteceded by an artificial abortion is due to tubal occlusion 3½ times as often as in cases of primary sterility; 6.1 times as often as in one child sterility and 7.7 times as often as in cases preceded by spontaneous mis-

carriages Eighteen out of 219 patients who had had one or more induced abortions became pregnant after utero-tubal insufflation as against 31 out of 239 patients who had had spontaneous miscarriages The fallopian tubes appear particularly prone to damage by the operation of artificial abortion; the uterine end and the isthmus are frequently sealed Tubal sterility following artificial abortion is of such great frequency that it appears to be next in importance only to gonorrhoea Apart from the well-known immediate dangers of an induced abortion, patients may well be warned against this operation because of the danger of permanent sterility

MEMORIAL TO DR CHARLES G STOCKTON

BY WILLIAM H ROSS, M D, BRENTWOOD, N Y

An address by the President of the Medical Society of the State of New York at the memorial service held under the auspices of the University of Buffalo on Sunday, January 25 1931 in honor of Dr Charles G Stockton President of the Medical Society of the State of New York 1909 1910 who died January 5 1931 aged 77 years

We have met here not alone to review Dr Stockton's career or to honor his life and his work, because that is already secure, but also to express to each other his influence on medicine and on the public medical service obligation of the profession We do this for the good that it will do to us His obvious accomplishments are so evident that they could be discussed as well by strangers as by those who knew him, but there are intangible influences in his life, not so easily seen by strangers and not easily put into words, that will run on and on in continued effect They are greater than anyone can tell because they are not measurable by words

Dr Stockton belonged to that class of medical men in whose lives there was more than medicine There is more than medicine in every doctor's life A doctor may awaken in an individual finer feelings than anyone else can Every great character in medicine, independently of whether he has exerted his influence in a wide field or in narrower lines, has exerted an influence beyond his own knowledge He has given an inspiration to those with whom he came in contact

If we can only realize that the profession of medicine is a social function, that it has done more for world betterment than any other profession, that it has influenced all civilization, we should begin to understand that there is something that we do not know, an intangible influence that we cannot measure because we cannot put it into words The real profession of medicine does not live unto itself There is no such thing as medical isolation Its human relationships are too important for that If medicine fails of full cooperation with other health influences and social needs and then if it should receive its precise share of fortune, good or bad, would we be proud of it?

I have been a student of the presidential addresses of all the presidents of the Medical Society of this State and of the social trends of the corresponding periods Among these addresses Dr Stockton's stands out Dr Stockton in his presidential address in January, 1910, published in the NEW YORK STATE JOURNAL OF MEDICINE of February, 1910 reflected an understanding of the social trends of twenty years ago and foreshadowed the greater social changes going on today When the history of the present decade is written, whether from the viewpoint of medicine only or to include the changes in industry and the recognition of social obligations, it will be different from that of any other decade in our history There will be no more outstanding page than the accomplishments of medicine in the prevention of disease and conservation of life

Let me quote from Dr Stockton's address at the close of his year's administration of the affairs of the State Medical Society

"The success of the physician has always depended upon his ability to convince people, and the doctor has a following in ratio to the extent of his command of public and private

confidence. In these days more than ever we are devoting ourselves to the education of the community, not alone individual members thereof, but society as a whole."

These words anticipated changes accepted today, that the greatest influence in the betterment of public health will come from health education; and when he said that, we have less difficulty in persuading people to adopt means to improve their health than we have in providing opportunity for it all, he foreshadowed problems that we are trying to solve nowadays by increasing the availability of scientific medical knowledge in the prevention of disease and conservation of health.

Let me quote Dr. Stockton's conception of a physician's burden:

"But we should remember that in proportion to the extent with which we command public confidence, we assume a burden of responsibility."

Nothing could foreshadow better the effort that is being made today to show the profession of medicine that times are changing; that social medical needs are increasing; and that the only difference and the reason for it is that the public character of medicine has increased and public opinion supports the effort to provide better for the health of the public.

Dr. Stockton realized the difficulties when he said: "Unquestionably there are difficulties for us to surmount, as there always have been and as there always will be. The road of the physician is likely to remain one fully beset with trials and unexpected obstructions, and for that reason we may predict for it a glorious future. The feeble and halting are not so likely to select medicine for a career, but the courageous and untiring worker will not hesitate to take the trail that shows the foot-prints of such splendid predecessors as have been ours."

The closing paragraph is an inspiration. He says, "Therefore, we have no right to complain of our times or our conditions, but rather we should rejoice that to us has come the opportunity of battling against obvious evils. There need be no fear that preventive medicine will ever remove the field of labor. It is evident that preventive medicine requires the best effort that we can put forth, so at most it only means transferring the activity from one side of the field to the other."

The wisest man is not the man who knows most of the present only, but he who can also see the farthest into the future. Dr. Stockton's vision of professional responsibility expressed twenty years ago has in it a remarkable lesson of the soundness of the present effort of organized medicine in this state to solve its great problems by adjusting medical relationships to all health influences and, also, that medicine owes a public duty to all health influences, to determine their soundness, to guide their advent, and to furnish leadership in medical matters. Unless we are aware of existing trends in health and sickness service and are able to develop a plan of medical action in advance of popular demand, we cannot expect to guide these movements toward better health by sound medical programs.

I cannot add to the effect of Dr. Stockton's words of twenty years ago and I would not detract by further effort. Therefore, may I close in the words of one who was his close, personal friend and at whose request Dr. Stockton wrote the introductory section on "Diseases of the Digestive Apparatus" in Osler's "Modern Medicine."

"Medicine is an art, not a trade; a calling, not a business; a calling in which there is exercise for the heart as well as for the head."

STRYCHNINE POISONING*

By JOHN AIKMAN, M.D., ROCHESTER, N. Y.

ALTHOUGH we have quite a full program, I am going to take a few minutes to call your attention to a cause of death in small children that seems to have received but little attention in New York State. This is done with the hope that the matter may be carried to the Legislative Committee of the State Society, which may, in turn, advise the passage of laws to better safeguard children against this danger.

Our attention was first called to strychnine poisoning in small children by having an opportunity to study two cases that died in Rochester. Briefly, the histories were as follows: On December 8, 1928, a strong healthy two-year old girl found and ate some cathartic tablets that had been given to her grandfather by the family physician. The parents had no idea that the tablets contained poison and did nothing until the child developed convulsions about 3 hours later. Only after careful questioning did the parents then remember about the tablets. In spite of any thing we could do the child died 2 hours after the onset of the convulsions. At autopsy, 3 tablets were found in the stomach. The tablets contained, Aloin ¾ gr., extract of nux vomica ½ gr., extract of belladonna ⅛ gr.

On May 4, 1929, a second case was seen with Dr. John Finigan. A boy 4 years of age who had previously been in excellent health ate 90 Hinckle's cascara tablets that had been purchased for adult use. The tablets contained, strychnine sulphate 1/60 gr., aloin ¼ gr., podophyllum ⅛ gr., extract belladonna ⅛ gr., cascarin ¼ gr., ginger 1/16 gr. He died about seven hours later with symptoms of both atropine and strychnine poisoning. In neither case were the parents aware that the tablets contained a poison and no marked precaution had been taken to keep them from the children.

We present here the results of our studies on this subject as concerns our own State; the review of the literature and facts concerning this matter in other States will be reported elsewhere. (Aikman, John: Strychnine Poisoning in Children. *J. A. M. A.*, 95:1661-1665, November 29, 1930).

We were able to secure from the State Board of Health an excellent tabulation of the deaths from strychnine poisoning in children in New York State exclusive of Greater New York. An average of 13 such deaths occur each year most of which are due to medicines taken by mistake. The type of medicine most often mentioned as a cause of death is the bright colored sugar coated tonic or cathartic tablet. One-half of the children were under two years of age.

The death rate in New York City cannot be shown because strychnine poisoning is not listed separately in the International list of causes of death. New York City records strychnine poisoning under No. 177 "Other Acute Accidental Poisonings (Gas Excepted)." The total number shown under 177 for 1926, 1927 and 1928 was 80 outside of New York City and 34 in Greater New York, showing that strychnine poisoning must be much less in the Metropolitan district. This is also indicated by the fact that but one case of strychnine poisoning in an infant was seen in 5 years on the Pediatric Service at Bellevue Hospital out of 13,500 admissions. (Hoppe, Louis D., *Arch. Pediat.*, 40:264, April, 1923.) New York families must for some reason be less likely to leave medicines about the house.

Study of this subject shows that strychnine poisoning is the most common fatal poisoning in small children. It is due to the careless habit of leaving attractive and pleasant tasting tablets about the home. Most of these tables are cathartics like A. B. & S., A. B. S. & C., and Hinckle's or tonic tablets containing strychnine or nux vomica. The amount of strychnine varies from 1/120 gr. to 1/60 gr. Several of these tablets produce toxic effects on a small child.

The laws in this State that control the sale of such tablets and even tablets containing strychnine alone are very lax. Hinckle's tablets containing 1/60 gr. of strychnine are on display in drug stores and can be purchased over the counter. The only warning required is the formula printed on the label. Laymen are quite unlikely to know the toxic dose of strychnine and have no knowledge that the tablets are dangerous to children. This is the condition that exists under our present pharmacy laws.

While the loss of life from this cause is not great, it far exceeds in this State the combined number of deaths from both tetanus and rabies for the same age groups.

The deaths occur in strong active children and are preventable. The following suggestions are made for the reduction of these deaths.

(1) Education of the public.

(2) Poison labels or special labels as to danger for children.

(3) Restriction of sale of strychnine except on prescription.

(4) Elimination of the colored sugar coating on the tablets. If tablets containing strychnine or nux vomica were never so coated, fewer cases of poisoning would result. The bitter taste would prevent the ingestion of a dangerous amount of the drug.

THE HEALTH COMMISSION

The preliminary report of the Governor's Health Commission, abstracted on page 230 indicates the probable lines along which public health legislation will be promoted. In general the suggestions refer to the actions to be taken by municipalities in order to bring the benefits of medical service within reach of all classes of people.

The trouble with scientific medical service is not in its production by research, or its storage in available physicians. The defect lies principally in its final distribution from family doctors to needy individuals. The suggestions consist mainly of providing the means by which practicing physicians of a community may deliver medical service to the needy on a sound economic basis. Physicians will do their own peculiar work well, if the municipalities will provide them with workshops in the form of hospitals, sanatoriums, and clinics, and administrative facilities, typified by county health departments.

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—NO. 16

The studies of organized medicine in New York State bring to the surface a steady stream of details of medical problems which the existing organization seems not to be able to meet promptly.

Medicine has not gone far enough in understanding that there are social problems for which it is imperatively necessary to find rather prompt solutions. Medicine is still guided too largely by principles that were stated in the address of the President of the New York State Medical Society at the annual meeting in 1879; President Roosa said, "Our functions as a society are chiefly performed by our scientific work. Our legislative duties are fortunately few. We have no alliance with the State that is more than honorary."

This was the viewpoint of organized medicine fifty-two years ago. Contrast it with the present when we are trying to increase the availability of scientific medical knowledge for the prevention of disease; to solve the problem of adequate medical care for major illness for those whose incomes do not lift them far enough above providing for the necessities of life and for whom there must be provided sooner or later some form of sickness insurance; and to arouse the interest of the mass of the profession in better organization for the solutions of the great social problems. The steadily increasing public interest, unless actively supported, guided, and led by organized medicine, will stimulate the State to exercise its parental function.

We need to realize that there is more than science in medicine today. Just look over the list of legislative bills already introduced—a chiropractic bill—one to remove the limitations on physiotherapists—a variety of bills increasing the number of occupational diseases to be made compensable to the point where all conditions that may be said to arise out of injury affecting health or ability to work are to be considered compensable—one on health insurance.

The proper functioning of the Public Welfare Law is dependent upon the activity of organized medicine. It is now going ahead well in Suffolk County since the Economic and Public Relations Committees of the County Medical Society arranged a conference with the Public Welfare Commissioner and the superintendents of the hospitals in the county. The meeting was called at one of the hospitals, (a lunch was served at noon). It was announced at the beginning that the conference was called in a friendly spirit to work out the mutual problems of the county government, the hospitals, and the medical profession. The results were satisfactory in every sense. Doctors will be paid their usual fees, hospitals their ward rates, regulations formulated to cover unusual features. At the close of the conference, the Public Welfare Commissioner expressed his appreciation of the conference and said that he was sorry not to have had the benefit of conference before. In this county conferences will be held from time to time until a plan is perfected that will make this law a blessing to the indigent and a satisfaction to the medical profession.

In one county of New York State the hospitals are charging different rates for public welfare cases. The Commissioner is sending the cases to the one charging the lowest price, though it is located in one end of the county. This county needs the spirit of public relations. Who can do it but the organized profession? Here is an example of a weakness in medical organization or such an impasse would hardly have occurred. How can medicine learn that its problems must be approached by the power of unanimous opinion?

Almost weekly I find somewhere in the State an example of weakness in medical organization—a committee of a county society responsible for some definite duty that hardly knows that it is alive. This is not lack of ability. It is lack of interest. How can medical relationships ever become what they should be until the profession of medicine, as a whole, takes an interest in present day trends in relationships to health and sickness service?

The present year of great effort by all the committees of the State Society will bear fruit. The intangible influences of this effort will flow on. Slowly tradition, conservatism, and prejudice will break down. When we awaken to our responsibility that there is more in medicine than the cure of disease after it starts, we will get out of the rut and begin to act.

Great as the change has been in organized medicine, it is not sufficient to meet the rapidly developing problems. We must provide for better functioning of our existing organization. We must realize that we are slowly coming nearer to the conditions that have confronted medicine in the older countries. If we are to avoid the dangers to professional independence, it will not be by shutting our eyes to the present day social trends or by destructive criticism of the effort of social organizations and the government to meet problems of health and sickness service.

WILLIAM H. ROSS.

STOLEN OUTFITS

The traffic in stolen medical outfits is larger and more widespread than is generally realized. The following letter has just been received from the Cameron Surgical Specialty Company, 1674 Broadway, New York City. (Telephone, Columbus 5-6672.):

"A complete Cameron diagnostic outfit worth $500 was stolen from a Cameron salesman's car on January 30th. If anyone attempts to sell you a Cameron outfit, make sure the person is a Cameron representative. A reward is being offered for the recovery of the outfit and arrest of the thief.

"A purchaser of stolen goods becomes liable."

This outfit will probably be offered for sale at half price or less. Let no doctor be deluded into the belief that he can purchase such an outfit with impunity. He will ultimately need to send for a new part, such as a lamp or a valve; and when he does, the Company will look him up in the list of owners of Cameron outfits, for this Company keeps an accurate list of all purchasers of its important wares, as do most other manufacturers. If the purchaser is not recorded, he will be investigated, and possibly subjected to a lawsuit, if the outfit is identified. The fact that he was innocent as a purchaser will not protect him from due process of law in the recovery of stolen goods.

A racket is also worked in connection with the disposal of instruments and office equipment of a deceased physician. A solicitor calls upon the executors of the estate and offers to take the goods and undertake to sell them. Possibly he may pay a small deposit in order to disarm suspicion; but he takes the more valuable and portable part and that is the last the executors see or hear of him. Medical societies and journals are frequently asked for advice in cases of this sort, but seldom is publicity made, for the identification of the goods is difficult or impossible.

The members of the medical societies appreciate the efforts of the instrument makers to design and supply them with reliable outfits, and are ready to subscribe to the following principles of mutual protection:

1. Have no dealings whatever with an unknown salesman who offers you a bargain in a standard instrument of expensive make.
2. If knowledge of such a salesman comes to you, report him to a reputable firm dealing in the line of goods which he offers.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Public Health Work—The first committee on Public Health of the reorganized State Medical Society made its report to the House of Delegates on January 29, 1906, which was printed in this Journal of February, 1906, as follows:

"The annual conference of the State health officers at Albany is an admirable summer school of three days' duration in which every man can receive valuable information if he attends. But, however valuable the papers and how eminent soever are the instructors, and though every one of the State medical officers attend, the educative period is so brief that men of the highest general attainment in medicine could not become masters of the technical knowledge absolutely necessary to him who would realize in himself the highest possibilities of modern sanitary science. Attention has been called in at least two reports of this committee to the system inaugurated in England in 1866, and which has worked to the great advantage of the British Empire, by which only those who have pursued especial courses in Sanitary Science, and who have received the additional degree of "Doctor of Public Health," could be selected as physicians to local boards of health. In this day of specializing in medical and surgical practice it should excite universal comment that there is little evidence of a tendency among younger practitioners to make State medicine a specialty. No other field is so rich in possibilities of doing valuable service. If this field is not attractive because it does not offer a sufficient pecuniary reward to amply sustain an ambitious young man, we have ourselves to blame. The value of the services rendered by an intelligent physician of the first class to the public is capable of recognition by the public, and it will be so recognized in the near future. We urge once more that the Regents of the University of the State of New York investigate this subject and make such provisions as are necessary for the inauguration of supplementary courses in public health, at the completion of which the physician shall receive the degree of D.P.H., and that the laws of the State be so amended that the attainment of that degree shall be a necessary qualification for every physician who would qualify for the position of physician to a board of health or as health officer to any city or village in our State."

MEDICAL PROGRESS

Creosote Enemata to Prevent Postoperative Pulmonary Complications.—After a 3 year test of the so-called Weiler creosote enemata as a prophylactic against pulmonary complications, H. Gaudier reports that he has found this method better than auto- or stock vaccines or any other form of treatment thus far employed. To a glass of lukewarm milk are added 40 drops of tincture of creosote. After a preliminary cleansing enema the creosoted milk is introduced slowly into the rectum, where it is to be retained one hour. Children are given only 5 to 15 drops in a correspondingly smaller amount of milk. The injection is in no way irritating, but in exceptional cases 5-10 drops of laudanum may be added. The patient receives 2 such enemata daily for 3 days previous to operation, and a final enema early on the morning of operation, sufficient time being allowed for its expulsion before the patient is taken to the operating room. In cases of emergency operation the injections may be administered for 3 days following operation, at the same rate of two a day. The taste of the creosote is quickly perceived by the patient, and its odor can be detected in the expired air, saliva, perspiration, and urine. Where the operation is performed on the rectum itself, creosote may be administered subcutaneously twice a day for 4 days, in doses of 20 drops in camphorated oil. The treatment is especially recommended before operations on the stomach, liver, or kidney, and in patients who because of their age and general condition are predisposed to pulmonary complications. Gaudier has used it systematically and has never had any untoward pulmonary symptoms such as he used to observe in the past. Where general anesthesia has been employed, he gives in addition an oxygen inhalation for 10 minutes at the close of anesthesia.—*Progrès médical,* October 30, 1930.

A New Method of Treating Status Asthenicus.—A. Barbé says that he has had great success in 33 cases of asthenia, or, if one prefers the term, psychasthenia, depression, or simple melancholia, in which the picture presented is one of lassitude and weakness, absence of will power and of courage, especially upon getting up in the morning. This morning predominance is in fact the main symptom that these cases have in common. The patients indulge in self-pity and discouragement during a large part of the day, but become brighter and approximately normal toward evening. Examination reveals no organic lesion of the nervous system or any other apparatus. Whether the condition begins in intellectual fatigue or physical lassitude, it soon presents the picture of both. It occurred to Barbé that the fact of the regular morning recurrence of this state of inanition might be overcome by the simple device of giving a glass of lukewarm milk regularly once an hour until noon, from the time of waking in the morning. In order to make the patients take the treatment seriously, he gave orders for them to add 3 drops of tincture of cratægus to each glass of milk. It is very evident that this small amount had no physiological effect upon the patient, but exerted a purely psychical influence. In the great majority of the cases excellent results were observed in a very short time. At the end of 2 weeks or a month they had not only got back their good spirits but had also recovered a good appetite and could resume their usual occupations. Strange to say, this taking of 1-1/2 to 2 liters of milk every forenoon did not at all decrease the desire for food in the middle of the day, but on the contrary produced ravenous appetite, many patients stating that they had never been so hungry before. Naturally if the mental troubles are of a serious order the treatment has no effect, which is a proof that states of asthenia and of true melancholia are two distinct conditions, only apparently related.—*Progrès Médical,* November 29, 1930.

A New Digitalis (Digitalis lanata Ehrh.).—A comparative study of *Digitalis purpurea* and of *Digitalis lanata* of Central Europe by Em. Perrot, P. Bourcet, and Raymond-Hamet has convinced these workers that while both have identical properties, the latter is appreciably more active in its effect. It has a content in active glucosides of 2.5 gm. per kilo, 1. to 1.5 gm. of which consists of a special crystallized glucoside with cardiotonic properties to which they have given the name *dilanin.* This substance appears to be different from both the digitoxin of Smith and the glucosides of Mannich. It is a white crystalline body which fuses at 182°C., and which, although not seeming to be absolutely homogeneous, cannot be mistaken for crystallized digitalin Nativelle nor for digitoxin. As occurs with *Digitalis purpurea,* the stabilized leaves are subject to rapid changes during desiccation. Experiments in dogs to prove that dilanin is not crystallized digitalin showed that the minimum lethal dose (using the method of Trévan) is 0.40 mg. per kilo body weight for dilanin, and 0.50 mg. for crystallized digitalin Nativelle. By the method of Rowe the average lethal dose was found to be 1.19 mg. for dilanin and 1.69 mg. for crystal-

lized digitalin. These figures prove that the two glucosides are different and that dilanin is the more toxic. In view not only of the extremely weak content of *D. purpurea* in the crystallized glucoside but also of the variability of this content according to the geographical source of the plant, it is possible that *D. lanata* will in time supplant it, since there seems to be no way to bring about a standard rational culture of the former. In fact, *D. lanata,* which is much richer in active principle, is already widely cultivated. Pharmacologic researches are now in progress with a view to determining whether, like crystallized digitalin, dilanin is fixed permanently on the cardiac muscle, and whether its toxicity is approximately as great by mouth as by intravenous injection.—*Bulletin de l' Académie de Médecine,* November 4, 1930.

The Effect of Epinephrine in Angina Pectoris, with Report of a Case.—James E. Cottrell and Francis Clark Wood review the recent report of Levine, Ernstene, and Jacobson, in which it is suggested that the effect of subcutaneously injected epinephrine may be used as a means of differentiating between true angina pectoris and other conditions attended by pain similar to that of angina. They found that in the great majority of instances an injection of 1 c.c. of 1:1000 epinephrine produces in a patient who suffers from angina pectoris a typical attack, accompanied by a sharper increase in the systolic blood pressure, pulse pressure, and pulse rate than is obtained in control subjects. There is also noted a uniform increase in the amplitude of the T wave in Lead II in patients with angina. In the only case in which the authors used this test, a Russian Jewess, aged 43 years, the problem presented was to distinguish between true angina pectoris and anginoid pain of neurotic origin. A subcutaneous injection of 1 c.c. of 1:1000 epinephrine resulted in a violent attack of substernal pain persisting for over eight hours; in collapse, unconsciousness, bradycardia, cessation of respiration, and a fall in blood pressure from 170/115 to 80/60. Electrocardiographic changes suggested added myocardial damage. In a review of the case to discover any differences in the patient or in the procedure as compared with the patients and the method used by Levine and his associates, it was found that the patient had sinoauricular block before the test. She also had chronic hypertension not present in the cases described by Levine, and the site of the injection was massaged. The case suggests that the therapeutic use of epinephrine in patients who may have angina pectoris requires great care. This caution probably applies likewise to ephedrine.—*American Journal of the Medical Sciences,* January, 1931, clxxxi, 1.

Insulin Shock and the Myocardium.—William S. Middleton and William H. Oatway, writing in the *American Journal of the Medical Sciences,* January, 1931, clxxxi, 1, state that, as in diabetes mellitus there exists an inability of the tissues to utilize glucose, a certain handicap falls on all the tissues including the heart. According to Cruickshank and Patterson, the normal heart utilizes 1.87 mg. of glucose per gram hour, whereas the diabetic heart burns only 0.9 mg. Furthermore, in clinical diabetes there is a notable tendency to atherosclerosis. A serious obstacle to proper function is thereby thrown on the myocardium through impaired coronary circulation. In view of such disadvantages insulin imposes a further theoretical chance of injury through the induction of hypoglycemia to which may be added other adverse effects. Experimental and clinical evidence indicates that this hazard is real. Accordingly, the authors investigated the cardiovascular reactions in 11 patients during the height of their clinical manifestation of insulin shock and during periods of complete freedom from symptoms. In none were there subjective or objective evidences of organic heart disease, though in several subjects varying degrees of sclerosis were demonstrable in peripheral arteries. The most notable finding was the regularity of a decrease in the height of the T wave in all three leads and also a decreased amplitude of this wave. There was in addition a tendency of the P waves to be decreased in height, but less markedly. There was an increase in the auriculoventricular conduction time in a smaller proportion of the cases. The blood pressure changes for the entire group showed a tendency for the systolic as well as the diastolic reading to be decreased. When the clinical picture of insulin shock was attended by hypoglycemia the electrical changes appeared to be more decisive. Patients below forty years of age showed a definitely increased tendency to have a delayed A-V conduction time. Because of the gravity of these changes in the presence of myocardial lesions, particular caution is enjoined in the use of insulin in such patients. Where any question as to the myocardial competency exists, the avoidance of hypoglycemia must be insured by adequate coverage of insulin through concomitant intravenous glucose injection. The practice of inducing insulin shock for whatever purpose is unphysiological, and in view of possible myocardial damage its occurrence cannot be condoned if avoidable.

Growth and Cardiac Defects.—In order to demonstrate that an inhibition of growth is due to severe cardiac defect, Werner Gottstein says that three conditions must be fulfilled: (1) The cardiac defect and the nutritional dis-

turbance it produces must be the *sole* cause of the dwarfed growth; endocrine disturbances constitutional defects, and familial dwarfism must be excluded. (2) Clinical findings must establish a severe and long-continued disturbance of circulation, which can be shown by an indisputable history to have preceded temporarily the stoppage of growth. (3) The somatic measurements must prove that the size does not fall within the normal limits of deviation. The most valid observations are naturally made in persons of adult age who in childhood had cardiac defects, since these give the necessary period for study. The question can in reality be answered only by a comparison of the growth development of uniovular twins, one of whom is healthy while the other has a serious valvular heart defect If the cardiac twin exhibits a retardation of growth, this speaks *in favor* of an adverse influence of the circulatory disturbance upon growing tissues Two 13-year-old twin brothers with identical faces and fingerprints furnished the author with a basis for such comparison. One was in perfect health, while the other had a cardiac defect following an infection five years previously. A recurring endocarditis had been under observation for over two years, and the roentgenogram showed a great hypertrophy of both ventricles. However, the growth curves and anthropometric measurements showed almost no differences between the boys, and they therefore speak *against* any restraining influence of a circulatory disturbance caused by valvular defect. To be sure, the objection may be raised that insufficient time has elapsed to justify a judgment. The real test will come after the onset of puberty. The case proves only the power of endogenous growth urge from the ninth to the fourteenth year of life. Gottstein has already shown in earlier studies that the functional capacity of cardiac children is often less implicated than that of adults, due perhaps to the fact that the peripheral circulation of the child does not readily fail. A circulatory disturbance must be very severe to restrain the urge to activity and to growth of the child.—*Klinische Wochenschrift,* December 20, 1930.

The Role of Glandular Fever in Clinical Medicine and Pathology.—The existence of glandular fever as a morbid entity, says Emil Schwartz, in the *Klinische Wochenschrift* of December 13, 1930, has been firmly established by observations covering the last 10 years. It is an infectious disease well defined both clinically and epidemiologically, produced by a lymphotropic virus, and characterized by fever, swelling of the lymph nodes, enlargement of the spleen and, especially, by a changed blood picture, in which an initial leucopenia or slight polynuclear leucocytosis passes over into a second phase with 12,000-20,000, or even more, leucocytes per cubic millimeter, 70-80 per cent of which are lymphocytes. These are large and are frequently immature or atypical forms, with nuclei often consisting of a loose network with several nucleoli. Large numbers of these cells exhibit a tendency to turn into plasma cells. Eosinophils are nearly always present, and monocytes in large numbers, but these are as a rule damaged, and look like azure granules. Even myelocytes may be found. This blood picture persists with great intensity during the period of fever, and returns only slowly to normal, being sometimes still demonstrable after months. After an incubation period of about a week, the attack begins clinically with fever, soon followed by swellings of the lymph glands, first behind the angle of the jaw, then the anterior cervical glands and those of the nape, the supraclavicular fossae, the axillae, and groins. The spleen is palpable on the 3rd or 4th day 2 or 3 finger breadths below the margin of the ribs, and is characterized by a pecular resistance. The liver, too, may be felt below the ribs in some cases. Occasionally the condition is complicated by angina at the end of the first week, which may be follicular, pseudomembranous, or ulcerous. No specific bacillus has been found. Glandular fever attacks almost exclusively children and young persons under 30 years of age. The first lesson taught by its recognition as a disease entity is that what has heretofore been known as a lymphocytic reaction (not in a morphologic but in a pathogenetic sense) must undergo a complete remodelling.

Celiac Disease.—Leonard G. Parsons, writing in *The Lancet,* January 10, 1931, ccxx, 5602, states that the characteristics of celiac disease are: (1) The passage of feces containing large amounts of fat, ranging from 40 to 60 or even 80 per cent of the dried feces; (2) wasting and stunting of growth, amounting to infantilism; (3) abdominal distention; (4) anorexia and certain other nervous symptoms, such as muscular tenderness said to be due to peripheral neuritis; (5) deficiency symptoms—in infancy osteoporotic bone with rickets, which disappears as the stunting in growth becomes established, though it not infrequently reappears at a later stage. Other deficiency symptoms which may be present are tetany, scurvy, and edema. There is little doubt that many of the symptoms of celiac disease are the consequence of avitaminosis, resulting from defective alimentary absorption. Parsons made a study of the blood fats of normal children as compared with those suffering from celiac disease which afforded no evidence to support the view that the increased fecal fat in celiac dis-

ease is due to increased excretion of blood fat. The most probable explanation of the low blood fat and low blood sugar curves that were found is that they are due to defective absorption in the intestine. The secret of successful treatment is based on the facts detailed above. It is essential that a high protein diet be given with a moderate amount of carbohydrate, a very low or absent fat content, and an adequate supply of vitamins, salt and water. The three phase diet, employed with considerable success by John Howland, best fulfills these conditions. In the first phase protein skimmed milk is given. The second phase consists in the addition of bovril or other form of beef juice from which the fat has been removed, and other proteins, such as egg albumin, small quantities of rabbit, or chicken breast. In the third phase the amount of proteins is increased, and small quantities of carbohydrate are added, such as ripe banana, zwieback, grapenuts, and potato crisps without fat. Finally well-cooked cereals, such as rice and arrowroot, in small amounts are allowed. Vitamin B is supplied by giving marmite and vitamin D by ultraviolet irradiation, or by giving in the dry form irradiated ergosterol. The administration of carotin, closely related to vitamin A, is well worth a trial.

The General Mechanism of Growth and of Newgrowths.—Robert Hirsch says that he has demonstrated by experiments in 320 rabbits and white mice that during the period of youth, that is, of rapid growth, the growing organs have a high capacity for oxide reduction (in reduced glutathion) while that of the blood is low. As the animal grows, the concentration in reduced glutathion of the tissues diminishes progressively, while that of the blood rises. Growth stops when stable equilibrium between these two factors is reached. Attempts were made to determine whether in tissue of low capacity for oxide reduction, of an organism that has completed its growth, certain causes could not be set in motion to bring back this capacity at a given point of the tissues. It was found that any chronic irritation exercised upon an adult tissue (one, that is, whose potential of oxide reduction in reduced glutathion is low) causes the potential of oxide reduction to rise to a figure equal to that of a young tissue. Tar and arsenic, by causing a chronic intoxication, lower the oxide-reducing power of the blood to a figure approximating that of the blood of a young animal. Consequently, if tar is repeatedly painted upon the same tissue experimentally, it creates anew a difference in capacity for oxide reduction between this tissue and the blood, equivalent to that which exists in a young growing animal. If this is maintained over a sufficient period it seems to produce a lysis of cellular barriers and a proliferation similar to that of normal growth, with a progressive drop of oxide reduction toward that of the blood. It is therefore seen that in a tissue whose potential of oxide reduction has been thus artifically increased, a gradual fall of the potential takes place until it approaches that of the blood, whereupon a proliferation occurs according to the law of growth just stated. Studies are still in progress to determine whether the cause of cancer is the same in man.—*Bulletin de l'Académie de Médecine,* December 2, 1930.

A Little Recognized Source of Fatal Carbon Monoxide Intoxication.—In the *Journal de Médecine de Lyon* of November 20, 1930, F. Naville and Ch. Soutter describe a singular mode of carbon monoxide poisoning that sometimes occurs when a large wash boiler is used over the flame of a gas stove. The formation of carbon monoxide appears to be the combined result of two factors: the smallness of the space between the burner and the bottom of the boiler, and the large extent of surface covering, and tending to stifle, the flame. An obstacle thus hinders the free escape of the gas from the holes of the burner, resulting in a diminished aspiration of the air which should be drawn into the gas pipe to mix with the gas before the latter flows from the burner, and also in a diminished secondary mixing with air after the gas escapes. In addition the flame is cooled down by licking the floor of the boiler, in which is a large quantity of cold water requiring considerable time to heat. Illuminating gas is a compound of hydrogen, hydrocarbons, and carbon monoxide, in which the characteristic odor is given by the hydrocarbons. These are completely burned and thereby dispose of the odor. But the carbon monoxide is only in part consumed, and the residuum confers toxicity upon the product of combustion. The conditions responsible for fatal poisoning that has been known in several cases to occur under these circumstances are: (1) the large size of the vessel over the fire; (2) the considerable time necessary to heat the contents; (3) the narrow space between the vessel and the fire, and (4) the insufficient aeration. Experiments by Harber and by Meyer have demonstrated conclusively the production of carbon monoxide under receptacles in contact with the flame of the gas. It is present in enormous proportions in the cooled flame when the aeration from the primary mixing is insufficient, being 14 to 18 times that normally present. Prophylaxis lies in the invention of a better type of stove, and the warning of the public to have their rooms properly ventilated.

LEGAL

CRIMINAL LAW—CONFESSION SECURED BY THREATS AND VIOLENCE CONDEMNED

By LORENZ J. BROSNAN, ESQ
Counsel, Medical Society of the State of New York

In the administration of the criminal law in this country, every defendant is presumed to be innocent until he has been proven guilty beyond a reasonable doubt; and the Constitution of this State guarantees to every defendant in a criminal case a fair and impartial trial. Our courts are extremely zealous in criminal cases to preserve and guard the defendant's constitutional rights. While it is true that under our laws some of the guilty escape, it is better that that be so than that a single innocent person be unjustly punished.

We cannot fail to sympathize with the task of prosecuting authorities and officers of the law whose duty it is to arrest and prosecute vigorously those charged with the commission of a crime. Certainly in this day their task is not an easy one. The menace of the gunman, thief and racketeer is ever present in every State of the Union.

While it is true that no right-thinking man desires a criminal to escape punishment, it is equally true that we do not and cannot countenance the so-called third-degree methods employed by some police officers and prosecuting attorneys, either through mistaken zeal or through a desire to further their own interests. When a person has been arrested in a homicide case, it is customary for the police or the prosecuting authority of the County where the crime is alleged to be committed to seek to exact from the person so arrested a confession. Very often the only evidence which the police are able to secure is circumstantial in its nature and, realizing the difficulty of securing a conviction on circumstantial evidence, an attempt is made to buttress the people's case by securing from the defendant a written confession.

In practically every case where such a confession is secured, the defendant's counsel upon the trial seeks to exclude such confession on the ground that it was involuntary and was made only by reason of direct physical violence or threats of physical violence on the part of the police or prosecuting authorities. In many instances this claim is entirely without foundation, but our courts have had before them cases where the facts disclosed that the alleged confession was by reason of the circumstances under which it was exacted an involuntary confession. In such instances, where the confession has been admitted by the trial court and the trial has resulted in a conviction of the defendant, our Court of Appeals has consistently reversed such conviction, serving notice upon the police and the prosecuting authorities that convictions obtained by such means will not be upheld by the court.

The rule of law applicable to confessions in a criminal case is very simple, and may be thus stated:

"Only where a fair question of fact is presented should the jury be permitted to determine whether the confession is voluntary. If there is no such conflict and if the evidence points clearly to the involuntary nature of the confession the judge should exclude it as without evidence to support it."

A recent case considered by the Court of Appeals illustrates the principle here enunciated. A woman was strangled to death in her apartment at some time late Saturday night or early Sunday morning. The defendant was taken into custody by the police officers Sunday afternoon at a place some thirty miles from the scene of the crime. When arrested, he asserted his innocence and claimed that he could not have committed the crime as he was some thirty or forty miles from the scene of the crime, at the time when it was claimed that the crime was committed. He was taken to the police station on Sunday at midnight and questioned by the District Attorney, and to the District Attorney he again asserted his innocence. After questioning him for nearly an hour, the District Attorney departed leaving the defendant in the hands of three police officers. Thereafter, about six o'clock on Monday morning the defendant wrote on a card: "I kill ....." At about noon of the same day a stenographic record was taken of an interview with defendant by an Assistant District Attorney at the station house, in which he again said that he killed ....., but refused or was unable to state why or how he killed her. Another stenographic record was made of an interview at the District Attorney's office at about five o'clock in the afternoon, in which the defendant said: "I can say I killed her because she tried to break up my home" and "I don't remember a thing what happened there. I will plead guilty, I am willing to go to the electric chair for it."

The defendant testified that one of the police officers struck him on the jaw and knocked him to the floor; that the other two pulled his hair and knocked him about with blackjacks, kicked

him, cursed him, threatened to kill him, and made him write: "I kill ....." because they menaced him with further abuse if he refused; that he was still under the influence of fear when he made the later statements, so that he made no complaint to the Assistant District Attorney or the District Attorney.

The following day the defendant was arraigned in the Homicide Court and was committed to the county jail. The next day he complained of pain to the warden. The warden called a physician who examined him. As to the defendant's condition at that time the examining physician testified:

"Q. Now, doctor, will you tell this jury what your examination disclosed?

"A. I found echymoses, that means black and blue marks, over the right arm, with some swelling of the arm, with a hemetoma over the middle of the arm. A hemetoma is a little collection, or tumor of the blood. There were several abrasions over the right elbow, and right forearm. Abrasions are superficial scratches. There are livid stripes over the right farearm and back of the right hand. There are echymoses, black and blue marks, over the left arm, also over both eyelids on the left eye; over the left malar bone, that means the cheek bone here (indicating); there were some abrasions in the right temporal region, that is, up here (indicating)—

"The Court: Witness indicates by placing his hand on the left temple.

"A. (continuing)—There were a few echymoses over the back of the neck, and he complained of pain on manipulation of the head. There are some echymoses over the right scapula; that is the shoulder blade. There were echymoses over both sides of the back, and in the left lumbar region, that is, the left loin, in the left lower axillary region—the axillary region is the side of the chest, and the left lower axillary region would be the lower part of the side of the chest—there were echymoses over the right buttock, and over the front of the right thigh and over the front of the left thigh and over the back of both thighs, there were some abrasions of the right leg."

This evidence means that his body was covered with black and blue spots and lumps or swellings, caused by a fusion of blood under the skin, which might result from a beating. The doctor also saw the black eye which the defendant had.

Two or three days later, over the objection of the District Attorney, the defendant's counsel procured an order that the defendant be photographed in a nude condition. These photographs were introduced in evidence and corroborated the testimony of the examining physician.

The Court of Appeals held that the confession in this case was an involuntary one, and that as a matter of law the trial court should have excluded the confession instead of submitting it to the jury as a question of fact to determine whether it was voluntary or involuntary. In reversing the judgment of conviction the court said:

"After denying his (the defendant's) guilt, from the time of his capture until six o'clock the following morning, defendant suddenly writes on a card: 'I kill .....' Was his change of mind due to reflection and repentance under the long-continued questionings and exhortations of the police officers * * * or did they scare him into making it? He gives no details of the killing, either because he cannot or because he will not. One might consider, as bearing on the question of his guilt and the voluntary character of his confessions, why he was thus reticent. He made to the police officers a bare admission of guilt. They are unable, as was the District Attorney, to get more out of him except his statement that he was at the apartment of the deceased. He comes out of the long interview with the officers with palpable evidence of the application of physical force to his body. Nothing but the merest supposition suggests that his eye was blackened or his body bruised when he was first brought to the station house. When he was taken to jail, his body bore evidence of severe beating and bruising.

* * *

"It has been said: 'One is driven to the conclusion that the third degree is employed as a matter of course in most states, and has become a recognized step in the process that begins with arrest and ends with acquittal or final affirmance.' * * * The practice in England seems otherwise. Statements made after arrest in answer to questions by police officers, if legal evidence (as to which the law is not settled), are cautiously received (citing a case). Lawless methods of law enforcement should not be countenanced by our courts even though they may seem expedient to the authorities in order to apprehend the guilty. Whether a guilty man goes free or not is a small matter compared with the maintenance of principles which still safeguard a person accused of crime. If torture is to be accepted as a means of securing confessions, let us have no pretense about it but repeal Section 395 of the Code of Criminal Procedure and accept all evidence of all confessions however obtained, trusting to the jury to winnow the true from the false. As long as the section remains in the Code, the courts are bound to give as full protection to an accused as the evidence warrants."

In so holding, the Court of Appeals again reiterates the fundamental principle underlying the administration of the criminal law, "Whether a guilty man goes free or not is a small matter compared with the maintenance of principles which still safeguard a person accused of crime."

ALLEGED NEGLIGENCE IN PRESCRIBING MERCURY INJECTIONS

In this case the plaintiff called at the office of the defendant doctor complaining of a thickening of the tendons of his right and left hands, numbness in the balls of his feet and a feeling of heat in his toes. He had no pains in his legs, however, and no bladder difficulty. His physical examination showed that the pupil of his right eye was fixed to light and that it was irregular, and the left pupil was similarly abnormal, though not quite so slow in its reaction to light. There was slight swaying in the Romberg position, and the reflexes in his arms and legs were entirely lacking. On the basis of this examination and with the history that some years previous the patient had suffered an attack of what he called rheumatism in his legs, the doctor made a diagnosis of cerebrospinal syphilis of the tabes dorsalis type, together with a Dupuytren's contraction of the hand. The doctor concluded that the patient was either a chronic alcoholic or suffering possibly from the first stages of paresis.

The doctor advised him that in order to treat him properly it would be necessary to extract some fluid from his spine, to which the patient consented. Thereupon ten c.c. of spinal fluid was withdrawn, and a Wasserman test based on this spinal fluid and also on the blood of the patient gave negative findings. In spite of such findings, the doctor considered him a case of long-continued cerebrospinal syphilitic infection in which the condition had lasted for so long a period of time that the Wasserman test had become negative.

The doctor suggested that the patient undergo a series of mercury injections, followed by sodium iodide. Seven injections of mercury were given, each of which caused slight constitutional reactions and local tenderness over the site of injection as is usual. The patient then notified the doctor that he wished to discontiue the treatment as he was confined to his home and was being treated by another doctor for sickness which he claimed to be due to the mercury injections.

Suit was thereafter instituted by the patient claiming that by reason of the improper diagnosis and treatment of his case, he had become greatly damaged. The plaintiff failed to press the case, and a motion to dismiss the complaint was subsequently granted for that reason, thereby terminating the matter in the doctor's favor without trial.

ALLEGED NEGLIGENCE IN FAILURE TO COMPLETE OPERATION

In this case the plaintiff consulted the defendant doctor, who specialized in surgery especially regarding conditions involving the circulatory system, and gave a history of having had his right leg amputated below the knee about a year previous. The patient explained that the amputation had been performed because of gangrene, and he feared that his other leg was in about the same condition that his right leg had been before the amputation.

Upon examination the doctor determined that the patient was suffering from thrombo angiitis obliterans, a condition of the outer covering of the arteries which prevented circulation and tended to cause thrombosis involving both the whole leg and the stump. The doctor decided that the only relief for this condition was an arterial sympathectomy (Leriche operation). To this the patient consented and entered the hospital, where in preparation for the operation the doctor gave the patient intravenous injections of 5% saline solution, and caused heat treatment to be applied to the patient's legs. The patient was placed under a local anæsthesia of novocaine and the doctor proceeded to incise the leg over the popliteal artery. At that time the patient became restless and complained of the pain, and he was put under a general ether anæsthesia. The doctor proceeded to make an incision six inches long over said artery, exposing it, and then discovered that the artery was thrombose and that the thrombosis extended down to the foot. He then decided that it would be useless to continue the Leriche operation and did not make any attempt to strip the outer covering of the artery, but caused the wound to be closed and sutured it in the usual manner.

The incision healed nicely and the patient left the hospital in apparently somewhat better shape than when he entered.

The patient instituted suit against the doctor, charging that because of his negligence the ultimate result was that gangrene set in and it became necessary that his left leg be amputated. The plaintiff claimed in his complaint that the improper treatment on the part of the doctor consisted of commencing an operation to restore circulation in his left leg and failing to complete that operation which greatly aggravated the condition from which the plaintiff was suffering.

After the case had been instituted the plaintiff's attorneys did nothing to press the case and at the end of about three years a motion was made on behalf of the defendant to dismiss the action for want of prosecution, and the matter was terminated in the doctor's favor without a trial.

NEWS NOTES

NEW YORK STATE HEALTH COMMISSION, PRELIMINARY REPORT

The following abstract of the preliminary report of the New York State Health Commission appointed by Governor Franklin D. Roosevelt, on May 1, 1930, has been prepared by Dr. William H. Ross, a member of the Commission, and President of the Medical Society of the State of New York. It summarizes the recommendations submitted by each sub-committee, and deals chiefly with matters presenting urgent need for legislative action. The Commission will formulate a final report later in the year.

STATE DEPARTMENT OF HEALTH

In the organization and function of the State Department of Health, the Commission believes that New York State stands second to no other state in the Union. One of the most far-reaching results of the 1913 Commission was the creation of a Public Health Council, whose important accomplishment has been to create the Sanitary Code and prescribe qualifications for those appointed to direct public health activities. It has thus had great influence in promoting uniformity of health service.

In special contrast with the efficiency of the State Department of Health the Commission finds that the local health organizations are antiquated and inadequate. More specially trained personnel is required to stimulate and coordinate the individual small communities. Especially does the Commission recommend that the town and village units of today be organized and administered under a county unit plan. It directs attention to the effect the great advancement in methods and means of communication and transportation and the unparalleled advancement in science have had upon the conditions of living, particularly in the rural areas, and concludes that it will be easier to conduct a county unit today than it was to conduct a town and village unit fifty years ago. It cites the county health unit as possessing the following advantages over the present system:

1. The unit of population is sufficiently large to permit the employment of trained personnel.
2. One responsible board will be substituted for the many town and village boards of health, the county nursing committee, county milk inspection committee, county clinic committees, and board of managers of county laboratories.
3. A plan of continuing health service can be developed for the whole county, and all of the health personnel can be mobilized to meet emergency conditions in any part of the county.
4. Duplication and over-lapping of effort which now exists will be prevented, and better health protection can be furnished for present expenditures.
5. The relative needs for various types of health service in the county can be determined, and available public funds allotted in proportion to these needs.
6. School nursing activities now lacking in many rural schools can be furnished by nurses employed by the county board of health.
7. If school medical inspection is made a function of county boards of health, this important activity can be conducted more efficiently on a county-wide basis with trained personnel than under the present system.
8. Through the permissive provision under which tuberculosis control activities may be administered by the county board of health, this activity can be directly coordinated with other health services. This is particularly desirable in the smaller counties.
9. Under the permission granted to cities and large villages to join the rest of the county for purposes of health administration further coordination of health work on a county-wide basis is made possible. Such a union is desirable, especially for those cities and villages centrally located in the counties, and those of less than 50,000 population.
10. New and much needed health activities not now carried out and not possible under the present system can be undertaken.
11. Maternity and infant hygiene measures can be organized and efficiently conducted.
12. Treatment facilities for the control of the venereal diseases can be provided.
13. The sanitary quality of milk can be assured through a county-wide inspection service.
14. The sanitary quality of water supplies can be supervised through a county sanitary engineer.
15. Modern epidemiological methods can be applied for control of the communicable diseases in place of the present ineffective sys-

tem. Toxin-antitoxin, smallpox vaccination and other activities can be conducted by personnel provided for these other services

16 Less intimate state supervision and fewer direct services from the State Health Department will be required because of the better local organization.

In concluding its observations on the state and local (rural) health administrative machinery, it makes the following recommendations:

1. That the appointment of county boards of health be required in all counties.
2. That all villages of less than 5,000 population be included in the jurisdiction of the county board of health, and that the inclusion of larger villages and of cities be permitted upon the consent of the county and the city or village authorities.
3. That local health officers as assistants to the county health commissioner be continued in office for the term for which they previously have been appointed, and thereafter in the discretion of the county board of health
4. That at least three physicians be placed on the membership of the county board of health.
5. That the county health commissioner devote his entire time to the duties of his office in counties having a population under the jurisdiction of the board of health of more than 30,000; and that in the counties having less than 30,000 population the district state health officer be detailed by the State Commissioner to act as county commissioner.
6. That the effective date for the appointment of county boards of health be not later than July 1, 1931, and the appointment of county health commissioners be not later than January 1, 1932.
7. That laws relating to local boards of health be amended so as to abolish all town boards of health, consolidated health districts, and village boards of health in villages of less than 5,000 population not later than January 1, 1932.
8. That the public health law be amended to remove all reference to town boards of health, consolidated health districts and village boards of health for villages of less than 5,000 population.
9. That the county health commissioner be given concurrent power with the county board of health to abate nuisances affecting public health.
10. That the local health officer, upon the establishment of a county unit, be appointed deputy county health commissioner.

The following special recommendations are offered for the manner in which public health should be administered in cities under and above 50,000 population:

1. That in cities of more than 50,000 population health officers hereafter appointed be required to devote their entire time to the duties of their office.
2. That cities of less than 50,000 be encouraged either to employ whole time health officers at adequate salaries, or to include themselves in a county department of health for purposes of health administration.
3. That more adequate budgets be provided in cities in order that basic health activities may be efficiently conducted.

TUBERCULOSIS

The Commission finds the tuberculosis situation in the state far from satisfactory. Considering the number of years the state has been making special efforts to eradicate tuberculosis, there are far too many deaths occurring annually from the disease. It is conservatively estimated that not less than 20,000 active cases of the disease exist in up-state New York and another 25,000 cases in New York City. The disease still takes its largest toll in life and illness among children, among men in the period when their economic value is greatest, and among women at ages from twenty to thirty-five years, the period of their greatest fertility. In the light of these facts, the Commission concludes there is need for more adequate protection of infants and young children from infection, for further study of and more effective mitigation of industrial and occupational hazards, and for more adequate care of tuberculous patients and their families. In considering what the state can do to develop a more effective program, it came to the conclusion that further reductions can be effected by the use of available methods of combating the disease. These methods include:

(a) More adequate facilities for the discovery of active cases as sources of infection.
(b) Protection of persons, particularly infants and children, against infection from active cases in the family.
(c) The discovery of cases in their early stages.
(d) Efforts to remove or ameliorate these conditions of domestic
dustrial dusts,
lack of sunshine and light, and insufficient or unwholesome recreation,

All anti-tuberculosis activities must be co-ordinated to produce the greatest degree of efficiency. The weakest link in the chain today is the local rural health unit which is unable to discharge the responsibility for the discovery, diagnosis, reporting, and sanitary supervision of cases of the disease in the areas where they occur. Hospital facilities for the tuberculous are inadequate. Although the law authorizes counties to build tuberculosis sanitaria, there are still twenty-four counties with a total population of nearly one million with no tuberculosis hospitals, and six in which the existing institutions are not suitable for continued use. To remedy this situation the Commission makes the following recommendations:

1. That the state provide three additional state district tuberculosis sanatoria for all types of tuberculosis cases to be located geographically with reference to the unmet needs of sections of the state; and that the cost of maintenance of patients in these sanatoria be borne in large part by the counties served.
2. That legislation at this session authorize the establishment of these sanatoria, and appropriate funds for the purchase of sites and the preparation of plans.
3. That the administration of the state sanatorium at Ray Brook be centralized in the State Department of Health; and that when the other district sanatoria are constructed, the facilities at Ray Brook be available for incipient cases from New York City and all types of cases from surrounding counties.
4. That the state provide through the Department of Health and the district state sanatoria facilities for (a) cooperation with local health departments in the diagnosis, instruction and follow-up of patients; (b) scientific studies of tuberculosis; (c) instruction of physicians and nurses in tuberculosis diagnosis, treatment and care; (d) a uniform system of records for use by local health authorities.
5. That field activities for the control of tuberculosis be coordinated with other local health activities under county departments of health with the consultative assistance of the state; and with an adequate social service and relief program of local public welfare authorities.
6. That the Public Health Council be authorized to prescribe the qualifications for the position of chief medical officer of all public tuberculosis sanatoria in the same manner as for other public health positions.

VENEREAL DISEASES

The Commission will later make a more complete report upon the venereal diseases, but it is in possession of sufficient facts to warrant its making several very important recommendations. Syphilis alone ranks with cancer and tuberculosis as a chief cause of illness, death, and economic loss. More than two thousand patients in state mental hospitals are there because of a syphilitic infection. This represents ten per cent of the total admission to these institutions, and it costs $8,000,000 to provide the beds now occupied by these patients. Accurate methods of prompt diagnosis and speedy sterilization of infectious cases, the two possibilities of reducing the prevalence of the disease, are at hand, but they are not being employed as effectively as they should be.

Fifty-four local clinics in thirty counties treat more than six thousand patients annually, but twenty-seven counties have no clinics. The Commission makes the following recommendations:

1. That present laws be amended to provide for treatment of the venereal diseases as a public health problem, irrespective of whether or not the individual case be indigent or infectious.
2. That the county and city boards of health be required to provide facilities for the diagnosis and treatment of the venereal diseases, which meet the standards prescribed by the State Commissioner of Health.
3. That provision be made in the organization of county boards of health for the diagnosis, treatment, and follow-up of cases of the venereal diseases. If the county boards of health are not generally established with state aid, then it is recommended that state financial aid be given to encourage local boards of health to establish satisfactory facilities for the diagnosis and treatment of these diseases.

CANCER

Cancer ranks second as a cause of death in New York State. The state has for several years interested itself in the problem through its institution in Buffalo, where intensive research has been conducted and diagnostic service and treatment rendered many people. Recent additions to the amount gives this institution the largest single supply of radium of any institution in the world.

During 1930 a total of 1,697 new patients presented themselves at the hospital for examination, an increase of 247 over 1929.

It is to be hoped that individual counties will provide themselves with the following services

(a) Special hospitals for the treatment of advanced cases of cancer.
(b) Special departments of general hospitals where surgical and radiation therapy can be given by qualified experts.
(c) Out-patient services at these hospitals for the early diagnosis of cases.
(d) Intermittent clinics in the smaller centers of population where expert diagnostic skill can be made available.

The Commission offers the following recommendations:

1. That a division of cancer control be established in the State Department of Health, of which the State Institute for the Study of Malignant Diseases will be a part.
2. That existing studies now being conducted at the State Institute in Buffalo be extended to include field studies of the nature and extent of facilities available for the diagnosis and treatment of malignant disease.
3. That the State Department of Health conduct general public and professional education concerning the diagnosis and treatment of cancer; and that it cooperate with local authorities and agencies in the development of needed services for diagnosis and treatment of this disease.
4. That the present system of approval of public health laboratories and of bacteriologists be extended by the State Department of Health to include pathological laboratories and pathologists.

MATERNITY AND INFANCY HYGIENE

Among the more vital public health problems of the present day is that of adequate protection of the health of mothers and infants. In fifteen years infant mortality in New York State has been cut in half, but there has been no corresponding reduction in maternal mortality. The findings in New York State support the views of the White House Conference that pre-natal care is poorly organized and inadequately done, and in the country as a whole only a small portion of women receive "adequate pre-natal care." A more extensive report will be made later, but at present the Commission makes the following recommendations:

1. That in order to carry out a satisfactory program for saving the lives of mothers and children these activities need to be combined with a general health program for the community. For rural areas this can be done best through the organization of county health departments.
2. That more adequate pre-natal and child health activities should be organized and carried out in all local health departments.
3. That effort should be made to stimulate better teaching of obstetrics and pediatrics in medical schools.
4. That the benefits of the crippled children's act be extended to children of pre-school age who are suffering from orthopedic or other defects which are apt to handicap them seriously in later life.
5. That provision should be made for wider dissemination of knowledge of nutrition.
6. That facilities for promoting dental hygiene should be made available.
7. That the parents of pre-school children should be reached more extensively with health education.
8. That in the rural areas intensive efforts be made toward the vaccination and immunization of pre-school children against smallpox and diphtheria.

SCHOOL HYGIENE

The Commission is convinced that in the future there must be close cooperation between the Departments of Education and Health in providing for the health of the school child. The health authorities cannot relinquish any responsibility for the protection of health of the school child since it has a responsibility for the promotion of the health of all citizens regardless of age, and there must be a certain continuity of program planning. The joint responsibility can be outlined in the three following divisions:

1. Medical service to provide for periodic physical and mental examinations and correction of handicapping conditions, and medical guidance of the educational program which will emphasize the preventive health service through health teaching.
2. A program for the correlation of health serv-

ices of the school, home, and other community endeavors to the best interest of the pupil through community nurses and visiting teachers.

3. Health instruction and training aimed to equip such child to carry the full load of responsibility for his personal health by the development of sound health habits and practices as well as by the imparting of actual health information.

All medical examining and nursing services should be conducted so as to develop in pupils sound hygienic practices. The discovery of physical defects is of importance only when adequate steps are taken to provide for the correction of these defects. The Commission is of the opinion that full-time, trained personnel is needed in the administration of school health service. In the rural areas and small villages this service should be administered on a county or other comparable basis. And if county boards of health are organized, this could logically be made one of their functions.

ORTHOPEDICS

The state has accomplished much in the protection of its citizens against disability from infectious diseases, but the rehabilitation of the crippled child which, in a measure is comparable, is far from being adequately secured. The epidemic of infantile paralysis in 1916 left many cripples whom the State Department of Health, through a system of traveling clinics, has done much to prevent from becoming permanently deformed. A commission appointed by the state has made a careful survey of the state and secured legal provision for promoting the care, treatment, and education of such children. The present problem is to make available adequate service for the cases now requiring care, and steadily to increase that service until all those needing advice are found. The most hopeful possibility for the accomplishment of this aim lies in the development of the county unit. The Commission offers the following three recommendations:

1. *New York State Reconstruction Home.* It is recommended that the State Department of Health be made entirely responsible for the administration of the Reconstruction Home at West Haverstraw, and that efforts be made to affiliate it with several of the teaching medical centers of the state so that it may become a training center both for the physicians and the nurses in the orthopedic field.
2. *Unimprovable Cripples.* It is recommended that a separate building be provided at the Reconstruction Home with suitable facilities to care for such cripples.
3. *Legal Recognition of Orthopedic Division.* It is recommended that the designation of "Orthopedic Division" be legally authorized in the Public Health Law.

INDUSTRIAL HYGIENE

The most important phase of the health servicing activities of the state is assurance of safe and sanitary work-shop conditions for industrial workers. The industrial board has legal authority for formulating and enforcing rules and regulations for the protection of employees. The rules and regulations are prepared by advisory committees composed of representatives of employers and employees and qualified experts, and the material is collected by the Bureau of Industrial Hygiene. The bureau of workmen's compensation is doing much for the relief of the workman, but it is evident that if the schedule of disabling diseases arising out of employment were more general, the fields of source-prevention cooperation would be extended and encouraged, and a further reduction accomplished in the sum of personal disabilities and loss of productive services.

The Commission makes the following recommendations:

1. That the present requirement of the labor law, which makes it the duty of local health officers in villages and towns to inspect certain business offices and factories, be changed so that this duty is performed by the State Department of Labor in the same manner as now provided by law for similar business offices and factories located in cities.
2. That the present limited schedule of occupational diseases be extended to include other diseases arising out of employment.
3. That the State Department of Labor be given additional facilities to conduct investigations of health hazards in industry with a view to their prevention.

SANITATION

Greater progress has been made in reducing typhoid fever and other diseases caused by contaminated water and food than among any other groups of diseases. The State Department of Health now supervises 620 public water supplies, but it lacks definite authority to approve plans for construction of new plants. The State Department may also order municipalities to install and operate sewage treatment plants, but certain difficulties, among them increase of debt, prevent practical application of this authority. The discharge of industrial waste into streams presents a problem also in which the State Department of Health should have additional authority A modern water purification plant or sewage treatment plant requires competent local supervision; therefore, all operators of such plants should be required to meet qualifications prescribed by the Public Health Council.

Recommendations

1 That the laws be amended so as to give the State Department of Health specific authority to approve of plans for proposed new, and extensions to existing public water supplies, insofar as the sanitary quality of the water supply is concerned.

2 That the pollution of streams by industrial wastes not containing sewage be regulated in the same manner as such wastes which do contain sewage.

3. That specific authority be given and sufficient facilities provided for more intimate supervision of the sanitary conditions of state parks.

4 That the Public Health Council be given power by law to prescribe by regulations the qualifications of and grades for operators of water purification and treatment plants and sewage treatment works.

PUBLIC HEALTH PERSONNEL

The Commission makes the following recommendation with regard to the qualifications of personnel, recognizing that for efficient administration of the highly scientific public health laws of today a well-trained personnel is essential:

That the present authority of the Public Health Council to establish the qualifications of public health nurses and other personnel named in the law be extended to include operators of water purification plants and of sewage treatment works, pathologists in charge of approved laboratories, superintendents of public tuberculosis sanatoria, and other professional and technical personnel.

OTHER PUBLIC HEALTH PROBLEMS

In addition to the topics which are presented in this preliminary report, the Commission has embraced within its deliberations studies of the subjects of: Mental Hygiene, Medical Care, Public Health Nursing, Control of Communicable Diseases, Laboratory Service, Milk Sanitation, Dental Hygiene, Public Health Education, and State and Local Volunteer Health Agencies. The Commission is formulating a series of administrative recommendations in regard to many of these problems. There is no pressing need at this time, however, for legislative action on these subjects, and they are, therefore, excluded from this preliminary report.

SUMMARY OF MAJOR LEGISLATIVE RECOMMENDATIONS

The Commission submits herewith a summary of its major legislative recommendations, and urges their favorable consideration by the Governor and their submission to the legislature for action during its present session.

1. *County Boards of Health.* That the organization of county boards of health be required in all counties.
2. *City Health Administration.* That in cities of more than 50,000 population, health officers hereafter appointed be required to devote their entire time to the duties of their office.
3. *Tuberculosis.* That the construction of three district state tuberculosis sanatoria be authorized and that the administration of the state sanatorium at Ray Brook be placed under the State Department of Health.
4. *The Venereal Diseases.* That the Public Health Law be amended to provide for treatment of the venereal diseases as a public

health problem irrespective of whether or not the individual case be indigent or infectious.

5. *Cancer.* That a Division of Cancer Control be established in the State Department of Health.
6. *Maternity, Infancy and Child Hygiene.* That adequate measures for protecting the health of mothers and children be included in the program of every city and county health department.
7. *Crippled Children.* That the administration of the State Reconstruction Home at West Haverstraw be placed under the State Department of Health, and that a separate building be provided for unimprovable cripples.
8. *Industrial Hygiene.* That the inspection of certain industrial establishments in villages and towns be performed by the State Department of Labor instead of by local health officers.
9. *Public Water Supplies.* That the State Department of Health be given specific authority to approve of plans for proposed new and extensions of existing public water supplies, in so far as the sanitary quality of the supply is concerned.
10. *Stream Pollution.* That the pollution of streams by industrial wastes not containing sewage be regulated in the same manner as such wastes which do contain sewage.
11. *Public Health Personnel.* That the present authority of the Public Health Council to establish qualifications for certain public health personnel be extended to include other positions in the public health field.

CONFERENCE OF LEGISLATIVE CHAIRMEN

The annual conference of the chairmen of the Legislative Committees of the County Medical Societies of New York State was held in the DeWitt Clinton Hotel, Albany, on Tuesday, February 10, 1931, with the representatives of over thirty societies present, and Dr. Harry Aranow, of Bronx County, Chairman of the State Committee on Legislation, presiding. A morning session was held, beginning at 10 o'clock. Luncheon was served at one o'clock, and was followed by an afternoon session.

The first bills to be discussed were seven relating to workmen's compensation, including the establishment of a medical advisory committee as an adjunct to the council of the Department of Labor. This bill has been proposed for several years in succession, and if enacted, it would provide a means by which misunderstandings with physicians could be eliminated.

The chiropractors have introduced a bill legalizing the practice of their cult, and are pushing it more actively than in previous years. They were also active in the campaign previous to the last election, especially in New York City, and openly advocated the election or defeat of several candidates for the Legislature. They even distributed circulars asking such questions as the following: "What would you do if your doctor had given up a case as hopeless, when chiropractic could restore your child to health?"

One speaker suggested that, if some medical school should make a scientific investigation of the basis and claims of the chiropractors, and should issue an authoritative statement condemning the practice, the legislators would give heed to the opinion. But the representatives of the medical schools and the educational authorities have always taken the ground that all who practice the healing art, including the chiropractor, should be required to possess the same basic scientific knowledge that a physician or dentist, or veterinarian must have. The chiropractors are willing to agree to this provided only that those now in practice are exempted from the requirement. The bill is only a bold attempt to secure special business privileges for a few. The story of exemptions has always been that, if one cult is exempted, another cult will spring up and its backers will ask similar privileges. After the osteopaths, for example, had been granted exemptions, their successors, the chiropractors, arose with similar demands, and already the naturopaths are waiting for their opportunity,—and there are fifty-seven other brands in New York City according to a census made three years ago.

Another perennial bill is that of the so-called anti-vivisectionists, whose protection is extended only to dogs. This movement is maintained by an endowment without which it would soon die a natural death.

The conference took notice of a bill which authorizes the State Department of Education to establish depots for supplying alcoholic liquors for medicinal purposes. Several other bills were also considered, among them being one for preventing the mixing of babies in hospitals; one providing every birth certificate should contain the fingerprint of the mother and the footprint of the child; and one forbidding the sale of bichloride of mercury except on the prescription of a physician.

What will probably be the most important medical legislation of the year will probably be introduced within the next fortnight as the result of the report of Governor Roosevelt's Health Commission, whose recommendations are summarized on page 230 of this Journal.

LEGISLATION

The Committe on Legislation has adopted the plan of sending bills and descriptive letters to the county society Legislative Chairmen, and also a general bulletin from time to time. The following letters and bulletin have been issued:

January 19, 1931.

The first instalment of bills, as you will observe, contains only one stranger and the introducer of that is a familiar character.

Mr. Cuvillier has reintroduced his bill of former years, asking that the state establish compulsory health insurance. May we suggest that you review this bill anew and with a little more care than in previous years, simply because there are so many articles appearing in the magazines and newspapers today, either commenting upon the English system of health insurance or advocating some variety for America. It is well to remember, also that Governor Roosevelt appointed a commission last summer for the study of health and medical activities and it will report to him within the next month. We are eagerly awaiting that report. (See page 230.)

Mr. Vaughan has reintroduced his dog bill and Mr. Horn his amendment to the Workmen's Compensation Law.

The new bill is by Dr. Love. His scheme for maintaining the identity of babies is foolproof in our opinion.

May we ask again that each chairman endeavor to send us a comment upon each bill that we send out? It seems like asking a good deal, but you must remember that your committee in Albany is unable to determine the reaction of the various County Societies except through such comments as you and your committee may make. Give us your cooperation.

January 26, 1931.

Assembly Int. No. 227, by Mr. Doyle, would add a new section to the Penal Law regarding the sale and manufacture of bichloride of mercury and compounds thereof. Look this over carefully and let us know whether, in your opinion, such regulation would interfere with the practice of medicine.

The second bill, Senate Int. No. 211, by Mr. Mastick, is identical with the bill he introduced last year, known then as Senate Int. No. 32. We opposed the bill at that time. Do you feel that we should continue that opposition this year? If so, give us your reasons.

January 30, 1931.

Enclosed you will find another bill amending the Workmen's Compensation Law in relation to occupational diseases, Senate Int. No. 278-Hickey (Assembly Int. No. 451-Gimbrone).

Mr. Hastings has reintroduced, with some modifications, his medicinal liquor bill of last year, Senate Int. No. 263. As reported before, this bill has been referred to the Finance Committee.

Senator Downing has reintroduced, with some modifications, his bill of last year in the Senate-Int. No. 53 (Assembly Int. No. 344-Livingston), which would provide that all public employees be insured in a state fund and opportunity provided for insurance in the state fund by all employers in private industries. Last year we opposed this bill, as you will find by referring to your records.

February 2, 1931.

Enclosed you will find a bill introduced in the Assembly by Mr. Byrnes-Int. No. 432—amending the Education Law in relation to physiotherapists. The amendment you will find very objectionable and we recommend that you immediately file with your legislators the most powerful protest you can muster.

In addition, there are three other bills that are reintroductions. All of these bills were before the legislature last year.

Senate Int. No. 344-Cilano (Assembly Int. No. 442-Esmond), was carried last year by Mr. Baumes. We were in favor of the bill at that time.

Senate Int. No. 345-Cilano (Assembly Int. No. 441-Esmond), is a greatly modified reproduction of Assembly bill Int. No. 960-Byrnes, of last year.

Senate Int. No. 361-McNaboe, of New York City. This is the chiropractic bill that Mr. Porter carried last year. It has not been revised and contains the same objectionable waiver clause upon which we centered our opposition last year.

The chiropractors are sponsoring a bill as in former years, and are conducting an active campaign of publicity, especially in New York City. As usual they ask that all now practising the cult be licensed. They are perfectly willing to exclude all others from practising their brand of treatment. Physicians must be on guard lest the cultists succeed in their attempts to secure official recognition.

The physiotherapists are also actively campaigning for increased recognition, even to asking

that they be permitted to give x-ray and light treatments without a prescription from a physician. This amounts to a recognition of their diagnostic ability, which of course does not exist.

Physicians throughout the State can obtain information from the chairmen of the legislative committees of their county medical societies, for copies of all medical bills are sent to the chairmen.

BULLETIN NUMBER 2

January 28, 1931.

We have had quite a few letters from chairmen advising us that they will be present at the conference on February 10th. Hope that you haven't overlooked the matter, and that we will have the largest attendance we have ever had. We are going to have plenty of material to discuss at that time. (See page 236.)

Yesterday there appeared in the legislature the following bills:

Senate Int. No. 344-Cilano (Assembly Int. No. 442-Esmond), creating qualified psychiatrists.

Senate Int. No. 361-McNaboe—the Porter chiropractic bill of last year. Senator McNaboe comes from the 16th district, New York City.

Assembly Int. No. 432-Byrnes, amending the law with regard to the practice of physiotherapy. He would remove the limitations placed on the practice of physiotherapy by technicians and add the privilege of treating diseases by actiotherapy and electrotherapy, exclusive of the x-ray, and adding to the examining board a member of the New York State Society of Physiotherapists. Mr. Byrnes comes from the 12th district, New York City.

Assembly Int. No. 451-Gimbrone (Senate Int. No. 278-Hickey), is another bill providing for the treatment of all diseases arising out of employment. It is the third bill of this type to be introduced this year.

Copies of these bills will be sent out as soon as they are printed.

Senator Hastings has reintroduced his medicinal liquor bill of last year—Senate Int. No. 263—and it has been referred to the Finance Committee.

The Committee on Codes announces a hearing will be given on the Vaughan anti-vivisection bill—Assembly Int. No. 143—on Tuesday, February 24th.

HARRY ARANOW,
WALTER A. CALIHAN,
JOHN J. RAINEY,
Committee on Legislation.

HOTELS OF SYRACUSE

The next annual meeting of the Medical Society of the State of New York will be held in Syracuse, N. Y., June 1-3, 1931. The headquarters and meetings will be in the Hotel Syracuse. The rates in the principal hotels of Syracuse are shown in the following table:

	Room for One Person			Room for Two Persons			
	With Bath	Without Bath	With Shower	With Bath	Without Bath	With Shower	With Twin Beds and Tub
Hotel Syracuse.....	$4.00 and up	.....	.....	$6.50 and up	.....	.....	.....
Jefferson-Clinton.....	$3.00	$2.50	.....	$5.00 and $6.00	$4.00	.....	.....
The Onondaga.....	$3.00 and up	$2.50 and up	$3.00 and up	$5.00 and up	$4.00 and up	$5.00 and up	$6.00 and up
The Yates.....	$3.00	(With running water, $1.75) (With toilet—$2.25)		$4.00 and $5.00	(With running water—$3.00) (With toilet—$3.50)		

ASSOCIATED PHYSICIANS OF LONG ISLAND

The thirty-third annual meeting of the Associated Physicians of Long Island was held on Saturday, January 31, 1931, in Brooklyn. The organization consists of about eight hundred members from every part of Long Island. It has published its own organ, the *Long Island Medical Journal*, which was merged with the *Medical Times* at the beginning of this year. The objects of the Association are both scientific and social.

The program of the annual meeting was in two parts. An all-day session was held in the Methodist Episcopal Hospital at Seventh Avenue and Sixth Street, Brooklyn. The morning was given over to clinics, both medical and surgical, and to observation of the work of the several departments.

A luncheon was served at one o'clock by courtesy of the Hospital.

A business meeting was held at two o'clock followed by a scientific session at three o'clock. The scientific program followed the usual plan that has been successfully carried out by the Association for several years, eighteen members of the Hospital Staff giving five-minute talks on clinical topics. The program was as follows:

1. The Diagnosis of Acute Osteo-Myelitis. Dr. H. K. Bell.

2. The Arsphenamines in Syphilis Dr. John C. Graham.

3. Is Spinal Anesthesia a Plaything or a Necessity? Dr. Henry F. Graham.

4. Case Report: Dislocation of a Cervical Vertebra Dr. Donald E. McKenna.

5. Prevalent Hypothyroid Manifestations. Dr. Irving L Cabot.

6 An Unusual Case of Rectal Hemorrhage. Dr. Seymour Clark.

7. Maternal Mortality in 15,000 Cases of Midwifery at the Methodist Hospital. Dr. H. W. Mayes.

8 Gastro-Enterostomy. An Unusual Complication. Dr. Russell S. Fowler.

9. Moving Picture: Simple Procedures in Infants. Dr. Walter Watton.

10. Contrasting Types of Cardiac Dyspnea. Dr. Frank B. Cross.

11. An Acidotic Type of Dyspnea Dr. A. T. Mays.

12. Statistical Review of Accidental Hemorrhage in 10,000 Cases of Pregnancy at Methodist Hospital. Dr. Harvey B. Matthews.

13. Hemochromatosis. Dr. E. B. Smith.

14. Volvulus of the Cecum. Dr. Pierre Renaud.

15. Cerebral Hemorrhage of the New Born. Dr. Walter R. Coles.

16. Thrombophlebitis Following Tonsilectomy. Dr. Charles A. Anderson

17. Tumor of the Frontal Lobe—Case Presentation Dr. Harold R. Merwarth.

18. Roentgen Diagnosis of Gall-Bladder Disease. Dr. George W. Cramp.

H. D. Langworthy, M.D, Chairman

The evening session was held in the Montauk Club and began with a social supper, at 6:30 o'clock. This was followed by a presentation of the subject of "Oysters From a Modern Point of View" by Dr. Herbert D. Pease, of the Pease Laboratories, New York City, who has been engaged in research work for years under the auspices of the Oyster Growers and Dealers Association of North America, Inc. Dr. Pease gave an illustrated lecture on the living processes of the oyster, with special reference to its feeding habits and their relation to its wholesomeness as human food. Some of the modern dealers market their oysters by placing them in sea water which has been purified by filtration and chlorination, and in twenty-four hours each shell fish has passed enough water through its gills and stomach to free itself of all food materials. It will then keep longer under marketing conditions and is in prime condition.

Another process that acts for the protection of human beings is the fact that oysters close their shells tightly and hold them closed when the temperature of the water falls to 40° F.; and within a few days the process of digestion has destroyed the bacteria within the shell. They are then substantially sterile.

Dr. Pease also described researches which are now being carried on in regard to the vitamin content of the oysters and their value in anemia. The dark part of the oyster and the clam is an organ for the conduct of digestive operations. It is somewhat analogous to the liver of mammals and probably has the like effects The white part of the oyster also has the anti-anemic qualities of glands.

Mr. Howard W. Beach, of New Haven, Connecticut, President of the Oyster Growers' Association, showed two reels of moving pictures which had been made in the course of the research work of the Association and supplemented with some by the United States Government. These pictures were distinct and vivid and showed the whole process of reproduction from the extrusion of the ova and sperm from the adult oysters, through the stage of fertilization and the division of cells, the free swimming larvae, and finally the method of their attachment to a solid object, such as a stone or shell. The picture is of intense interest not only to physicians, but also to biology students in colleges and high schools. The members of the Associated Physicians of Long Island felt that the pictures and the lecture combined practical instruction and entertainment in a most happy manner.

The newly elected president of the Association is Dr. Henry C. Courten, of Richmond Hill, who succeeds Dr. Charles H. Goodrich, of Brooklyn. Dr. James Cole Hancock of Brooklyn was re-elected secretary for the thirty-second time.

BLOOD DONORS IN NEW YORK CITY

Hundreds and even thousands of persons in Greater New York are willing to sell their blood for transfusion purposes; and agencies have been formed for the purpose of supplying donors on short notice. The service is of such importance that the Department of Health of New York City has undertaken to examine and certify the physical condition of those who apply for registration in the agencies.

Regulations governing the licensing of agencies and the employment of blood donors were adopted by the Department of Health of New York City on November 21, 1930. Section 109 concerns the agencies and their duties in regard to records of donors.

Section 108 goes into great detail regarding the examination and certification of blood donors and their identification. It also requires every physician to examine the donor before taking his blood and to record his examination in a book carried by the donor, and also to report the transfusion to the Department of Health for the purpose of tracing the donor should occasion require. Making the record and the report is a service which one physician renders to another.

The record book carried by each donor contains twelve pages bound in cloth and card board covers. It carries a photograph and description of the donor, his physical tests, including the luetic, and a concise statement of his blood classification.

The book also has blank pages on which the physician employing the donor shall enter the results of a physical examination made by him, before taking the blood. If the donor is rejected because of a physical condition, the physician shall make an entry of the reason for the rejection. The book is a complete record of the donor's experience in giving blood.

The certification of a donor is no guarantee of his fitness in all respects. The doctor employing a certified donor is expected to make his own tests and record them in the donor's book. But a certification is evidence that the donor has been subjected to scientific tests and is safer by far than a stranger on whom no tests have been made.

The regulations of the Department of Health do not interfere with the privilege of a physician to use a relative or friend of a patient as a donor, the theory being that the family of the sick person knows about the physical condition of such a donor.

PHYSICIANS ART CLUB EXHIBIT

The fifth Annual exhibition of the New York Physicians Art Club will be held at the Academy of Medicine, 103rd Street and Fifth Ave., New York City, from February 14th to March 14th.

A cordial invitation is extended to all members of the medical profession who wish to show original work in the plastic or graphic arts to participate in the coming exhibition. Membership in the New York Physicians Art Club is not necessary in order to exhibit. Further details may be obtained by addressing, Dr. Louis C. Schroeder, Secretary, 50 East 72nd Street, New York City.

The previous exhibitions have been of great interest to physicians and to the public and have been described in this Journal.

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on January 21, 1931, was called to order at 9 P. M. the President, Dr. Gettinger, in the Chair.

Election of candidates being in order, it was moved and carried that the Secretary be instructed to cast one ballot for the following candidates for membership: Drs. Abraham L. Kornzweig, Jacques L. Kubrick, Morton R. Milsner, Milton I. Schwalbe and Edna Walck.

Reports of Committees being in order, Dr. Aranow, Chairman of the Legislative Committee of the Medical Society of the State of New York, appealed for the united cooperation of the profession in the matter of legislation this year.

Dr. Keller submitted his Annual Report as Treasurer.

Dr Magid, Chairman of the Committee on Medical Economics, reported relative to a plan of our Counsel for the collection of debts for medical service rendered by our members

The President reported on a meeting of the Presidents of the five County Medical Societies and the Director of the Academy of Medicine with the Commissioner of Health on January 5th The object of Commissioner Wynne in calling the meeting was to gain the constructive cooperation of the medical profession The Commissioner made some valuable suggestions, among which were that a committee be appointed consisting of representatives of the various County Medical Societies to consider questions concerning community welfare and the economic stability of the physician

The President also reported regarding a meeting of the State Committee on Public Relations, of which Dr Sadlier is chairman and at which our Society was represented by the Editor of our Bulletin, the President and First Vice-President The meeting was very interesting It discussed the question of educating the public on what the doctor is doing in order to gain the public confidence

Dr William Klein reported on the work being done by the Program Committee of the Bronx Tuberculosis and Health Committee The Chairman of this Committee is Dr Podvin, and its work is being guided largely by members of this Society Its purpose is to popularize immunization against diphtheria and for examination of the pre-school child As the campaign is to be carried on in the interest of the family physician as well as the public, Dr Klein appealed for the cooperation of the members

The Scientific Program then proceeded as follows

Papers

1 Salpingography A Review of Cases, Illustrated by Lantern Slides, Elsie Fox

2 The Diaphragm: Its Relation to Diseases of Contiguous Structures Illustrated by Lantern Slides Jacob Fierstein

3 Some Common Rectal Disorders Newer Considerations and Treatment, Frank M Frankfeldt

Respectfully submitted
I J LANDSMAN, M D, *Secretary*

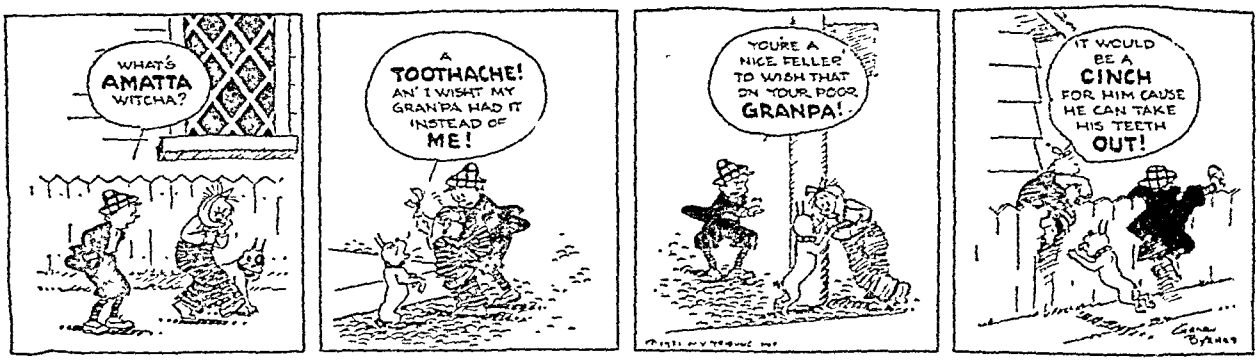
GREENE COUNTY

The regular meeting of the Society was held at the Saulpaugh Hotel, in Catskill, on the 13th of the month, at 7 P M

The business and scientific sessions were preceded by a dinner and the attendance was about fifty per cent of the membership, some of the men driving thirty-five miles to attend

The meeting was called to order at the conclusion of the dinner Dr Rapp, Chairman of the Committee appointed at the October meeting to further the plan to establish a County Hospital and a County Health Unit, reported the results of their efforts, and stated that there had been a meeting with the Trustees of the Hospital Fund and two meetings with the Board of Supervisors, that the matter was still being investigated by a special committee appointed by the Board of Supervisors and that a special meeting of this Board would be called later to act on the matter There seems to be a strong sentiment among the people for the proposed hospital

The County Health Unit does not seem to be well understood even among some of the physicians and a resolution was adopted following Dr Rapp's report that a special meeting of the Society be called to discuss this matter



Dr Charles L Willard, Treasurer of the Society, presented his resignation It was decided that as Dr Willard would end his term of forty years as Treasurer on March 12 1931, his resignation be accepted to take effect on that date, and that Dr Rapp be appointed acting treasurer until that time

Dr O D Chapman, Assistant Bacteriologist of the University of Syracuse, and Director of the Syracuse City Laboratory, presented a paper on Tularemia, illustrated by lantern slides This was delivered in a very pleasing and entertaining manner and was thoroughly enjoy by all

W M RAPP, *Secretary*

THE DAILY PRESS

Reg'lar Fellers — Bump Said a Mouthful — By Gene Byrnes

From the New York Herald Tribune of January 8, 1931

THE DEAR OLD PAST

We once told a musician that we envied his marvellous ear for chords, but he wished he could get out of it for every discord was torture to him. Modern comforts exact their own prices; and the happiest man is probably the one with the least care,—the primitive man. So thinks James J. Montague in the following verses in his column "More Truth Than Poetry" in the New York *Herald Tribune* of January eighth:

"One does not see the dinosaur
About the dooryard any more.
The pterodactyl's cheerful lay
Cannot be heard at all today.
Along the lane or thoroughfare
There never stalks a great cave bear.
And though one search the world around,
The missing link cannot be found.
In vain the hills and vales we scan
To see a Neolithic man.
And from the prairie and the lawn
The eohippus long has gone.
Fled with the world's departed youth.
The tiger of the saber tooth;
The mastodon's earth-shaking roar
Shakes down the forest trees no more.
The ichthyosaur's piercing eyes
No more are tilted toward the skies.
And only meaner creatures dwell
Upon the heights or in the dell.
But, backward though our eyes are cast,
We can't bring back the vanished past.
But only sorrowing sighs can raise
In memory of the good old lays,
Which must have vastly happier been
Than those we now are living in."

HEADACHE RESEARCH

The University of Illinois is conducting an investigation into periodic headache or migraine, and advertised for a patient for observation. The *New York Times* of January 7, commenting on the response, says:—

"In its search for a cure the research and education hospital offered $50 a month and board for a 'perfect' subject. The first day ninety-two persons applied. Out of a total of 750 applicants Theodore Roberts, 23 years old, an electrician, of Geneva, Ill., was selected. He believes his headache is 'the oldest and splittingest in existence.' It lays him low for a day or two every two weeks and has ever since he was 11. His headaches, he says, are 'dandies.' He inherited them from Mother.

"Now he is to be lodged in the quietest room in the laboratory, his sole task being to produce his headaches on regular schedule for three months. Should he fail to do so, it is uncertain whether the doctors will be distressed or delighted. Rest and quiet might prove a cure, but whether it is the one the research workers want is another matter.

SUBWAY NOISE

The Department of Health of New York City and other agencies are making scientific studies of noises, in which the subway officials are actively cooperating, through the engineering staff of the Western Electric Company. The New York *Times* of January 7 describes tests made in the Seventh Avenue Subway Manhattan with the following results:

"It was discovered at once on the trip to the Battery and return that the acceleration of the motors produced the greatest noise from a single source within the car. When the train left a station, where the noise found some escape in the open space of the platform, the roar increased. The greatest noise occurred as the motors accelerated in the tunnel while another train passed by. The maximum sound recorded on the trip was represented by 120 decibels.

"It was next discovered that more sound entered the microphone inside the car than through the one in the window, except when another train passed the test car. The greater din inside was attributed to the grinding gears, wheels and motors beneath the floor of the car and the fact that this noise could not easily escape from the closed car. The rattle in the structure of the old car also made its impressions on the instruments.

C. I. Conover, division engineer of the Board of Transportation who watched the tests, said the Board was studying several remedies offered for the reduction of subway noise, and that the findings of the acoustic engineers were expected to aid the board in reducing noise on the present lines as well as the new Eighth Avenue subway.

Studies are being made, it was said yesterday, on sound deadening materials for subway cars, motors, tracks and tunnels. One suggestion has been the use of a new worm gear to reduce motor noises, and pads to be inserted under steel rails."

HEALTH SERVICES TO COLLEGE STUDENTS

The principles and facts regarding health services to college students stated in an editorial in this Journal on page 91 of the issue of January 15, 1930, and in a report by Dr. Mitchell in the Journal of November 1, 1930, page 1283, are confirmed by the following news item from the New York *Sun* of January 8:

"Responsibility for the health of students was laid on the doorstep of the colleges today by the Federal Office of Education.

'The governmental agency, noting a failure on the part of land grant college authorities to learn of illness promptly warned officials they 'cannot free the schools of responsibility for the health of students.'

"'Adequate health facilities must be provided,' the report said. 'The present method of discovering and checking student illness is entirely inadequate. Only a few schools have any definite suggestions for improving this service.

'At present most of the schools rely upon the voluntary good auspices of fraternities, house mothers, solicitous friends or upon the students themselves to report illness.

'Where students lives for the most part, as they do in land grant institutions, in privately operated rooming houses, it is possible for a boy and less frequently for a girl to be seriously ill for days without causing solicitude upon the part of anyone.

"'There is no indication that the cause of students absence from classes is investigated until some untoward circumstance creates apprehension. There should be some means devised for remedying this serious defect.'

'Thirty-four of the colleges kept approved lists of rooming houses but only twenty-six inspected them, 'and this inspection is obviously in many cases too cursory to have real value.'

"Eighteen of the institutions reported examining food handlers regularly, while nineteen did not.

"'The laxness in examining employees who handle food is far from reassuring in the light of our knowledge of spreading contagious disease,' said the report.'

THE PRICE OF AN EAR

The 'Intern' column of the *New York Herald-Tribune* of January 10 contains the following story which may possibly be more entertaining than truthful:

'Here's a true hobo story from the Bowery. A gandy-dancer working out on Long Island, fell and bumped his head against the third rail, just about singeing off his right ear. The railroad company put him in hospital and employed expert plastic surgeons who after two months of artistic skin grafting work built him up an ear almost as good as new. The railroad paid the surgeons $1,400. The old gandy-dancer was outraged.

"Give all that dough to the docs! Why didn't you give it to me? To hell with the ear!"

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 14, No. 3. November, 1930. (Mayo Clinic Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, $16.00 net; paper, $12.00 net.

ASSOCIATION FOR RESEARCH IN NERVOUS AND MENTAL DISEASE. Vol. 6. The Cerebellum: an investigation of recent advances. Editorial Board Frederick Tilney, M.D. and others. Octavo of 649 pages, illustrated. Baltimore, Williams & Wilkins Company, 1929. Cloth, $10.00.

ASSOCIATION FOR RESEARCH IN NERVOUS AND MENTAL DISEASE. Vol. 8. The Intracranial Pressure in Health and Disease: an investigation of the most recent advances. Editorial Board Charles A. Elsberg, M.D. and others. Octavo of 519 pages, illustrated. Baltimore, Williams & Wilkins Company, 1929. Cloth, $6.00.

THE BEHAVIOR OF THE NEWBORN INFANT. By KARL CHAPMAN PRATT, PH.D. and others. Octavo of 237 pages. Columbus, The Ohio State University Press, 1930. Paper, $3.00. (Ohio State University Studies, Contributions in Psychology, No. 10).

TEXT-BOOK FOR NURSES: Anatomy, Physiology, Surgery and Medicine. By E. W. Hey Groves, M.D., and the late J. M. Fortescue-Brickdale, M.D. Fourth Edition. Octavo of 641 pages, illustrated. London and New York, Oxford University Press, 1930. Cloth, $6.50. (Oxford Medical Publications.)

PIERSOL'S HUMAN ANATOMY: Including Structure and Development and Practical Considerations. Ninth Edition revised under the supervision of G. Carl Huber, M.D., Sc.D. Quarto of 2104 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1930. Cloth, $10.00.

A TEXT-BOOK OF THE SURGICAL DYSPEPSIAS. By A. J. WALTON, M.S., M.B. Second Edition. Octavo of 720 pages, illustrated. New York, Longmans Green & Company, 1930. Cloth, $15.00.

OPERATIVE GYNECOLOGY. By HARRY STURGEON CROSSEN, M.D., F.A.C.S. & ROBERT JAMES CROSSEN, M.D. Fourth Edition. Octavo of 1078 pages, illustrated. St. Louis, C. V. Mosby Company, 1930. Cloth, $15.00.

MEDICAL JURISPRUDENCE: A Statement of the Law of Forensic Medicine. By ELMER D. BROTHERS, B.S., LL.B. Third Edition. Octavo of 309 pages. St. Louis, C. V. Mosby Company, 1930. Cloth, $3.50.

A MANUAL OF NORMAL PHYSICAL SIGNS. By WYNDHAM B. BLANTON, B.A., M.D. Second Edition. Octavo of 246 pages, illustrated. St. Louis, C. V. Mosby Company, 1930. Cloth, $3.00.

PHYSICAL DIAGNOSIS. By WARREN P. ELMER, B.S., M.D., & W. D. ROSE, M.D. Sixth Edition. Octavo of 903 pages, illustrated. St. Louis, C. V. Mosby Company, 1930. Cloth, $10.00.

MICROBIOLOGY AND ELEMENTARY PATHOLOGY: For the Use of Nurses. By CHARLES G. SINCLAIR, B.S., M.D. Octavo of 362 pages, illustrated. Philadelphia, F. A. Davis Company, 1930. Cloth, $2.50.

CHRONIC ARTHRITIS AND RHEUMATOID AFFECTIONS with recovery record by Bernard Langdon Wyatt, M.D., F.A.C.P. with the collaboration of Louis I. Dublin, Ph.D. Octavo of 141 pages. New York, William Wood & Company, 1930. Cloth, $2.50.

METHODS AND PROBLEMS OF MEDICAL EDUCATION. (Eighteenth Series). Quarto of 329 pages, illustrated. New York, The Rockefeller Foundation, 1930.

SURGICAL CLINICS OF NORTH AMERICA. Vol. 10, No. 6. December, 1930. (Philadelphia Number). Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, $16.00 net; paper, $12.00 net.

THE PATHOLOGY OF INTERNAL DISEASES. By William Boyd, M.D., M.R.C.P. Octavo of 888 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $10.00.

THERAPEUTICS, MATERIA MEDICA AND PHARMACY; The Special Therapeutics of Diseases and Symptoms, the Physiological and Therapeutical Actions of Drugs, the Modern Materia Medica, Official and Practical Pharmacy, Prescription Writing, and Antidotal and Antagonistic Treatment of Poisoning. By Sam'l O. L. Potter, A.M., M.D. Fifteenth edition, Revised by R. J. E. Scott, M.A., M.D. Octavo of 997 pages. Philadelphia, P. Blakiston's Son & Company, Inc. 1931. Cloth, $8.50.

ANNALS OF THE PICKETT-THOMSON RESEARCH LABORATORY. Vol. VI, The Pathogenic Streptococci: the role of the streptococci in scarlet fever. Quarto of 470 pages. Baltimore, The Williams and Wilkins Company, 1930.

RECENT ADVANCES IN BIOCHEMISTRY. By John Pryde, B.Sc., M.Sc. Third edition. Octavo of 393 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $3.50.

TRAUMATOTHERAPY: The Treatment of the Injured. By John J. Moorhead, B.Sc., M.D. Octavo of 574 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $7.00.

PRACTICAL RADIATION THERAPY. By Ira I. Kaplan, B.S., M.D. With a special chapter on applied x-ray physics by Carl B. Braestrup, B.Sc., P.E. Octavo of 354 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $6.00.

THE FACTOR OF INFECTION IN THE RHEUMATIC STATE. By Alvin F. Coburn, M.D. Quarto of 288 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1931. Cloth, $6.00.

A MANUAL OF THE COMMON CONTAGIOUS DISEASES. By Philip Moen Stimson, A.B., M.D. Octavo of 351 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $3.75.

BIOASSAYS, A HANDBOOK OF QUANTITATIVE PHARMACOLOGY. By James C. Munch. Octavo of 958 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1931. Cloth, $10.00.

BOOK REVIEWS

MANUAL OF PHYSIOLOGY By H WHITECHURCH LEE MD, BS FRCS, and DAVID DESMOND MD DSc FRCP Third Edition 12mo of 520 pages illustrated London and New York Oxford University Press, 1930 Cloth (Oxford Medical Publications)

This book on physiology first appeared in 1911 and is very much like the other standard works in that it is both in its academic presentation and in the information it offers to the student Its choice should therefore be left not to the recommendations of the reviewer but to the tastes of the individual purchaser

EMANUEL KRIMSKY

INJURIES TO JOINTS By SIR ROBERT JONES Bart KBE CB Third Edition 16mo of 176 pages illustrated London and New York Oxford University Press 1930 Cloth $2.00 (Oxford Medical Publications)

This manual originally written as a war manual has now passed through its third edition and is a book of almost two hundred pages In the first year of the war 1914 it was found that there were such divergencies of opinions and methods of the treatment of acute injuries and that as the mass of material was great that some method of standardization must be arrived at in treatment Sir Robert Jones through this manual was able to standardize traumatic injuries of the skeletal body and every English surgeon in Europe had one of these manuals in his kit It is proven that those same principles are applicable to the injuries of civil life that now occur in the great mechanical age following the war It is an excellent manual for both student and practitioners

JA C R

ALIMENTARY ANAPHYLAXIS (Gastro intestinal Food Allergy) By GUY LAROCHE CHARLES RICHET FILS and FRANÇOIS SAINT GIRONS 12mo of 139 pages Berkeley, University of California Press 1930 Cloth $2.00

This book is a translation from the French by Mildred and Albert Rowe It deals with food sensitization and is the most extensive summary in English of this subject Besides a discussion of the history and etiology of this phenomenon there is a long and detailed chapter on symptoms with a large list of case reports The authors devote much space to *pathogenesis with considerable* theoretical speculations They also report their results with *experimental food sensitization* The chapter on treatment contains many helpful clinical suggestions

WILLIAM S COLLENS

A SYNOPSIS OF SURGERY By ERNEST W H GROVES MS MD BSc (Lond) FRCS (Eng) Ninth Edition 12mo of 676 pages illustrated New York William Wood & Company 1930 Cloth $5.00

An immense amount of information is concentrated in the less than 700 pages in this book

The arrangement of subjects is along standard lines and quite complete The symptoms of Treatments are necessarily dogmatic but are in a rule up to date The section on Spinal Anesthesia could be re written with advantage No mention is made of the newer anesthetics such as Sodium Amytal

For the student seeking terse phrases to memorize or as a ready reference for the busy doctor the book is well suited Of readable size and fairly legible type its popularity is attested by its numerous editions the last being the ninth

STANLEY P THOMAS

HYPERTENSION By LESTER I GAGER MD Octavo of 158 pages Baltimore, Williams & Wilkins Company 1930 Cloth $3.00

As books on hypertension go this new addition by Dr Gager will no doubt find its place among the best Because of our incomplete knowledge of this subject we are necessarily obliged to deal with hypothetical speculations and theories The writer has made a serious survey of the literature and has classified 500 articles which have served as a basis for his text

The practitioner is primarily interested in treatment In the face of such discrepancies of opinion the evaluation of any single method of treatment cannot be recommended with any degree of confidence For example the use of nitrites is disparaged Liver extract is mentioned as a former remedy Diathermy so enthusiastically recommended by the late Clifford Allbutt as the best single method of treatment is not even mentioned

Dr Gager places faith mainly in two methods first the psychic approach and second the use of sulphocyanates

EMANUEL KRIMSKY

A TREATISE ON ORTHOPEDIC SURGERY By ROYAL WHITMAN MD MRCS LACS *Ninth Edition* Thoroughly Revised Octavo of 1085 pages illustrated Philadelphia Lea & Febiger 1930 Cloth $10.00

This astounding treatise on orthopedic surgery has passed through its ninth edition First published in 1901 it has grown from a text book of a few hundred pages to its present size of a thousand pages and it is of itself an indication of the present scope of orthopedics and the expansion of the subject in thirty years The original plan of the book is unchanged a compliment to the foresight of the writer but each subject treated is enlarged and so kept abreast with the latest thought Through its size it almost ceases to be a text book but has become a reference book however it is too well established as the standard text book in the English language to lose this position

JA C R

METHODS OF REFRACTION By JAMES THORINGTON A M M D Second Edition Revised 12mo of 406 pages illustrated Philadelphia P Blakiston's Son & Company 1930 Cloth $3.00

This work has been popular for so long that the name Thorington is almost synonymous with refraction in the minds of those physicians who practice ophthalmology In the special hospitals the interne reaches for Thorington as an answer to his every refraction problem

This new edition is concise as the first is written in the same clear manner One feels that he is being instructed in every detail and the statements are based on accepted evidence Obsolete matter and devices have been discarded and new ones inserted

All in all we feel safe in saying that Methods of Refraction still holds the first place among works of its kind We recommend it to every ophthalmologist young or old

J N EVANS

OXIDATION REDUCTION POTENTIALS By L MICHAELIS Octavo of 199 pages illustrated Philadelphia J B Lippincott Company 1930 Cloth $5.00 (Monographs on Experimental Biology)

The latest addition to the series of Monographs on Experimental Biology founded by Jacques Loeb is this volume on oxidation reduction potentials by Michaelis This book is a pioneer treatment of a new subject by a distinguished investigator

"Stimulated by his own experimental work on these questions, the author thought it timely and useful to venture to weigh the investigations so far made, to collect and to analyze their application to biological problems and to discuss the theoretical principles of oxidation reduction potentials with the hope that future work by others as well as by himself will be facilitated," says Michaelis in the foreword to the book.

The subject is treated under two main divisions. Part One, dealing with physico-chemical considerations, is a discussion of what is known at present regarding the mechanism and theory of redox potentials, together with a review of the experimental data obtained to date. Part Two deals with physiological applications. The physiologically important redox systems—cystein, glutathione, hemoglobin, cytochrome, Warburg's respiratory ferment and others are presented and discussed.

M. J. SHEAR.

THE PRINCIPLES AND PRACTICE OF HYGIENE. By DEAN F. SMILEY, A.B., M.D., ADRIAN G. GOULD, Ph.B., M.D., and ELIZABETH MELBY, M.A., R.N. Octavo of 415 pages, illustrated. New York, The Macmillan Company, 1930. Cloth, $2.50.

This book is intended as a text for use in the nursing curriculum. Every effort has been made in it to discuss subjects about which there is widespread misinformation. Simply written, yet presenting a mass of information in easily digestible form, it is worthy of recommendation to nurses for the study of personal hygiene.

FREDERIC DAMRAU.

APHASIA IN CHILDREN. By ALEX. W. G. EWING, M.A., Ph.D., with an introduction by E. D. Adrian, M.D. Octavo of 152 pages. London, Oxford University Press, 1930. Cloth, $3.50. (Oxford Medical Publications.)

We believe this book will be of great interest to the Otologist interested in the hard of hearing. About one-half of its pages are devoted to hearing tests and the amount and character of residual hearing in those who seem to have little or none. The remaining half is devoted to Aphasia, using the word in its larger sense.

It is a practical work based on experimental observation. It can be heartily recommended. W. D. L.

CLINICAL NUTRITION AND FEEDING INFANCY AND CHILDHOOD. By I. NEWTON KUGELMASS, M.D., Ph.D., Sc.D. Octavo of 345 pages, illustrated. Philadelphia and London, J. B. Lippincott Company, 1930. Cloth, $6.00.

This should prove to be a very helpful little volume for the practitioner's library.

The author handles such subjects as alimentary diseases, deficiency diseases, metabolic and allergic conditions in a brief yet concise manner, aided by graphs and illustrations.

Samples of diets are given in detail, also the tables of food values at the end of the book should not be overlooked.

THURMAN B. GIVAN.

EMBRYOLOGY AND EVOLUTION. By G. R. DE BEER. 12mo of 116 pages. London and New York, Oxford University Press, 1930. Cloth, (Oxford Medical Publications.)

This interesting little book will be eagerly read by students of Embryology and Evolution. It is really an essay in refutation of the theory of recapitulation of Haeckel by a series of progressive arguments in favor of the theories of Von Baer and his disciples.

In it the author seeks to prove that the modification of the shape of the adult animals in the successive generations during evolution could now be ragarded as a series of stages in the history of the race (phylogency) depends on modification in ontogeny (the series of shapes through which the individual passes in its own development from embryo to adult), and that changes in characteristics are due to the differences in the speed of the development of internal factors, mendelian factors, or genes. It also shows that the growth of genes can be changed by external factors.

This book is, in a way, a review of an enormous amount of work on this subject as evidenced by the Bibliography which covers nearly five pages.

The author's style is clear and concise and makes very interesting reading, and the book making is of the usual excellence of the Clarendon Press. G. G.

AMERICAN POCKET MEDICAL DICTIONARY. Edited by W. A. DORLAND, A.M., M.D. Fourteenth Edition, revised, 16mo of 837 pages. Philadelphia and London. W. B. Saunders Company, 1930. Flexible binding. Plain $2.00; Thumb Index, $2.50.

The new edition has been enlarged by about 3,000 additional terms and contains 60 more pages. This work continues to fill the needs of those desiring a medical lexicon in compact form. FREDERIC DAMRAU.

RADIUM AND CANCER. By DUNCAN C. L. FITZWILLIAMS, C.M.G., M.D., Ch.M., F.R.C.S. Octavo of 172 pages, illustrated. New York, William Wood & Company, 1930. Cloth, $4.50.

A text-book on radium therapy especially adapted for practical use. Avoiding discussion of perplexing theories, the author has presented the subject in a simple style, reviewing the physics, the effects of radium on the tissues, and the paraphernalia associated with its use. Abundant illustrations, many in color further elucidate the subject.

A complete description of radium therapy as applied to cancer of the mouth, pharynx, larynx, œsophagus, rectum, thyroid, breast, prostate, bladder, penis and skin furnish the physician with a reference handbook that will guide him in the use of radium.

HARRY MANDELBAUM.

STUDIES IN ETHICS FOR NURSES. By CHARLOTTE A. AIKENS, R.N. Third Edition, thoroughly revised. Octavo of 339 pages. Philadelphia and London, W. B. Saunders Company, 1930. Cloth, $2.50.

A splendid book. Could be read with benefit by all those who contemplate embracing the difficult rôle of trained nurse. It emphasizes the most important requirements of a nurse, good moral character, a capacity for obedience, loyalty and tactfulness, and above all a desire to be of real service to patients.

Every phase of a nurse's work, and difficulties likely to be encountered, are discussed in detail. Rules of conduct, not alone towards patients, but towards the vast number of people who form contact with a nurse, are suggested.

A tendency towards reiteration is the only fault to be found with the book. E. O. S.

MANUAL OF THE DISEASES OF THE EYE. By CHARLES H. MAY, M.D. Thirteenth Edition (Revised). 12mo of 461 pages, illustrated. New York, William Wood & Company, 1930. Cloth, $4.00.

As the author says in his preface to the first edition the great difficulty in preparing a book of this sort is to say enough but not too much. One feels that he has done this excellently well.

In the present edition the subject is well kept up-to-date in every respect, the most notable addition being part of a chapter devoted to the slit lamp and corneal microscope.

A new edition of this work is always welcome and this one is no exception. E. CLIFFORD PLACE.

DOSAGE TABLES FOR ROENTGEN THERAPY By Professor Friedrich Voltz Translated from the Second German Edition 12mo of 120 pages illustrated London Oxford University Press 1930 Cloth $2.50 (Oxford Medical Publications)

An excellent and instructive monograph for all interested in X-Ray therapy The author first distinguishes between physical versus biologic dosage and explains such terms as dosage quotient percentage depth dose effective and practical dose etc

Methods of measurement are briefly given with preference for the now generally accepted ionization instruments

The main purpose of the little book is the arrangement of sixty five tables the proper usage of which will permit the therapeutic adjustment of dosage under varied conditions The key dosage or practical unit must be biologically obtained following which from the proper usage of the tables any and all adjustments can be made

The author stresses the necessity of constant physical factors in the energizing apparatus and the control check up of the skin erythema dose (S E D) as best determined by ionoquantimetric study

MILTON G WALSH

CHRONIC NASAL SINUSITIS AND ITS RELATION TO GENERAL MEDICINE Based on the Author's Semi Jubilee in the University of London The Toll of Nasal Focal Sepsis on Body and Mind By Patrick Watson Williams Octavo of 221 pages illustrated New York William Wood and Company 1930 Cloth $5.00

This book which deals with the nasal accessory sinuses as cavities which harbor foci of infection is timely and of great value. Its value lies in the fact that most rhinologists are in accord with the writings of the author but require a book like this to stimulate them to better and more thorough work in the field of sinus disease

There are several procedures featured in this work which the author has spent a life time of concentrated effort to popularize and this is a fitting instrument with which to inform the rhinologists and others interested of the value of these procedures

The exploratory puncture and aspiration of previously introduced sterile fluid for culture from the maxillary and sphenoidal sinuses although not new have been practised by relatively few men The use of the nasopharyngoscope or a suitable endoscopic instrument for study of the nasal chambers is being used extensively by the specialists in this country

The greatest value of this book will be demonstrated in the stimulus that it will afford toward better and more accurate investigation of latent sinus disease There are times when one might infer that the author is perhaps too enthusiastic but his attainments and his contributions justify a whole hearted confidence and an interest on the part of all those who may be concerned with conditions which can be traced to a focus of infection Rhinology and Medicine in general owe much to Patrick Watson Williams for this fine contribution

M C MYERSON

DISEASES OF WOMEN By ten teachers under the direction of Comyns Berkeley M A M D Edited by Comyns Berkeley H Russell Andrews and J S Fairbairn Fourth Edition Octavo of 558 pages illustrated New York William Wood & Co 1930 Cloth $6.00

It is a pleasure to call attention to this the fourth edition of a work on gynecology by ten English authorities for it is a highly competent production which covers thus special field in its entirety The last word as to the most recent advances will here be found set down clearly and thoroughly The student practitioner and gynecologist will find style arrangement and content satisfactory

A C J

PRACTICAL MIDWIFERY FOR NURSES By PETHEL SOLOMONS M D F R C P I Octavo of 354 pages illustrated London Oxford University Press 1930 Cloth $2.75 (Oxford Medical Publications)

As the text book for lectures for nurses Although simple very practical and well illustrated it will not prove of great value to American nurses Normal labor is emphasized in Simpson position Much space is devoted to obstetric methods of infant resuscitation and the rules of the Central Midwives Board (Ireland)

C A G

THE MORPHINE HABIT By G LAUGHTON SCOTT M R C S M A 12mo of 94 pages New York William Wood & Company 1930 Cloth $2.25

Dr Scott maintains that the term morphinism but is misleading for the dependence of morphinism is as involuntary and relentless as thirst in the desert These addicts desire to be cured but cannot tear themselves away from it because it is too agonizing and painful On the basis of such an attitude he strongly advises that the actual withdrawal of the drug must be gradual He insists that harsh methods in treatment are responsible for most relapses The essential point is to accomplish withdrawal under gradually developed tolerance to belladonna and hyoscine with free and increasing use of luminal

EMANUEL KRIMSKY

THE GOLD HEADED CANE By WILLIAM MACMICHAEL M D A new Edition with an Introduction and Annotations by George C Peachey Octavo of 195 pages New York The Macmillan Company 1930 Cloth $6.50

The Gold Headed Cane was carried successively by Drs Radcliffe Mead Askew Pitcairn (William and David) and Matthew Baillie

The autobiography of the Gold Headed Cane was published anonymously (the author was Dr William Macmichael) in 1827 In the following year a new and enlarged edition by the author was published also anonymously

In 1884 a third edition was published edited by Dr William Munk who added considerable to the text and brought the narrative down to 1858 In 1915 an edition of text and illustrations of the second edition with an introduction by Sir William Osler and preface by Dr Francis R Packard was published in the U S

The present edition published in England in 1923 contains the text and illustrations of the second edition with the addition of six photogravure portraits of the possessors of the cane The edition is edited by George C Peachey who writes an interesting and instructive preface and adds many notes and annotations which throw light on matters referred to in the text

After the death of Dr Baillie who was a nephew of William and John Hunter his widow presented the Cane to the Royal College of Physicians where it still is

I O TRACY

A TEXT BOOK OF PATHOLOGY Edited by E T BELL M D Octavo of 627 pages illustrated Philadelphia Lea & Febiger 1930 Cloth $8.00

This book is written by Dr E T Bell and his associates in the Department of Pathology in the University of Minnesota It is essentially a text for medical students not a reference work for pathologists

The method of presentation is the conventional one first general pathology and then the pathology of special diseases and organs It is largely descriptive with occasional brief references to etiology and symptoms where such reference would be of value in teaching There are also references to the literature to aid the student in collateral reading The reviewer liked especially the chapters on the diseases of kidney and spleen

The volume is compact and the illustrations are mostly original from the collection at the University of Minnesota

E I SMITH

OUR NEIGHBORS

GRADUATE EDUCATION IN VIRGINIA

The House of Delegates of the Medical Society of Virginia on September 22, 1929, approved and adopted a report of the Committee on Medical Education and Hospitals, outlining a plan for bringing graduate medical education within reach of the physicians of the State through the cooperation of the State Medical Society, the two medical schools of the State, and the State Department of Health. The plans were reported in several issues of the *Virginia Medical Monthly*, abstracts from which were published in four issues of the NEW YORK STATE JOURNAL OF MEDICINE as follows:

December 15, 1929, page 1550.
February 1, 1930, page 188.
February 15, 1930, page 248.
April 15, 1930, page 486.

We have just received a booklet of 68 pages entitled "Post-Graduate Medical Education in Virginia," published by the University of Virginia, Charlottesville, Va. The booklet is a review of graduate work not only in Virginia, but also in other States. The Virginia booklet, part 1, opens with the sentences:

"Various plans in thirteen American states, Colorado, Iowa, Michigan, Minnesota, Missouri, New York, North Carolina, Ohio, Oklahoma, Oregon, Pennsylvania, West Virginia and Wisconsin, are known to have been inaugurated, with different degrees of success, as state programs of graduate medical education. Such data as could be found for each state have been summarized." In addition to these thirteen states, the NEW YORK STATE JOURNAL OF MEDICINE of 1929 and 1930, has abstracted descriptive references to graduate work from the Journals of seven additional states: Georgia, Indiana, Kentucky, New Jersey, South Carolina, Texas and Washington. The New York State Journal also quoted Kansas and Nebraska as seriously considering the establishment of graduate courses.

The Virginia booklet devotes three pages to the New York State Society courses, and says:

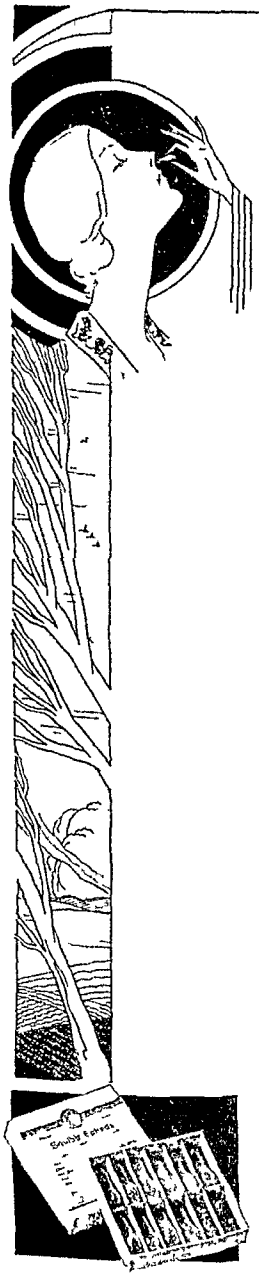
"New York has the largest undertaking, conducted by the strongest State Society, on the most generous plan." Its description of the methods in other States is a mine of information.

The *Virginia Medical Monthly* for January says editorially:

"Throughout the past year Dr. Hodges as Chairman of this Department has had an article on this page in each issue of the Medical Monthly, discussing the work of the Department (of Clinical Education), setting forth his plans for post-graduate medical education and appealing for cooperation to the Councilors of the State Society and to the leaders in the various Component Societies.

"It will be our policy to carry out the same plan with some changes which will, I think, add to the general interest of these articles. I shall at various times during the year ask other members of the Department of Clinical Education to contribute short papers giving their views on various phases of the work, and feel sure that this will add materially to the effectiveness of our whole undertaking. We may also from time to time ask specialists to discuss the importance of holding clinics in certain specified diseases. In some cases these may be teachers connected with one of our Medical Schools and in others general practitioners or specialists in private practice. I feel that this departure will meet with the approval of the membership of the State Society."

The January Journal also has the following news note:



"A post-graduate clinic for negro physicians of Virginia is announced by Dr. W. T. Sanger, president of the Medical College of Virginia. This is stated to be the first educational venture of its kind in the South and will be established by the College in connection with Saint Philip Hospital, Richmond. The instruction will begin June 16th. The negro physicians have been asked to decide upon the courses. The College has had the plan under consideration for several years and it has the endorsement of the Department of Clinical Education of the Medical Society of Virginia."

MEDICAL ECONOMICS IN COLORADO

A special meeting of the House of Delegates of the Colorado State Medical Society was called for January 17, to consider recommendations of the Committees on Public Policy and on Economics. The following report of the Committee on Economics is printed in the January issue of *Colorado Medicine*, to be presented to the House of Delegates:

"Our preliminary survey of the duties of this committee brings us to the realization that it is a more difficult task than one might suppose and

SQUIBB EPHEDS

A new and convenient Ephedrine preparation for the relief of colds

EPHEDRINE, an alkaloid prepared from the Chinese drug Ma Huang, has in recent years been recognized as a particularly effective drug for the relief of head colds.

Squibb now provides ephedrine compound containing an oil-soluble ephedrine salt in an oily base and marketed in a new, unique form under the distinctive name "Epheds."

Squibb Epheds are long-necked, flexible gelatin capsules for nasal application. Each capsule contains 8 minims of a 1/2% solution of ephedrine—in combination with aromatics and antiseptics.

Relief from congestion is promptly obtained when Epheds are used and the effect lasts for hours. Epheds provide a simple, convenient means of applying ephedrine into the nose without waste or the use of an atomizer.

Supplied in easy-to-carry boxes of one dozen, for use at home or when traveling.

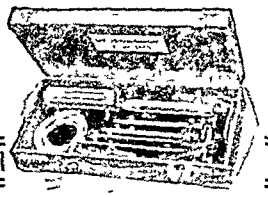
MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858.

ELECTRICALLY LIGHTED SURGICAL INSTRUMENTS

E. S. I. Co.

Your Guarantee of Quality



The trade-mark "E.S.I. Co." signifies not only the highest quality in electrically lighted diagnostic and surgical instruments but also the famous E.S.I. Co. Service that goes with them.

Included in the line are:

Nasopharyngoscopes	Cystoscopes
Transilluminators	Urethroscopes
Bronchoscopes	Rectal Instruments

You will find our catalog of electrically lighted surgical instruments extremely interesting. A free copy of it awaits your request. Send for it today!

COMMITTEE ON PUBLICATION

(*Continued from page 251—adv. xiii*)

of the question. Recently a statement was issued by the Committee on Public and Industrial Relations of that society which this Journal was requested to publish. It seemed unwise to comply with that request, lest favor might seem to be extended toward those supporting one view of the controversy. Now the opponents of the claims of this committee have prepared a reply to its statement, the publication of which has also been requested. Since both sides of the argument can thus be considered contiguously, it has been decided to publish both of these statements, which will be found on subsequent pages. They appear without the endorsement of this journal which maintains a neutral attitude so far as an expression of opinion is concerned."

The statement favoring contract practice was prepared by Dr. A. Macrae Smith, of Bellingham, President of the Society of Industrial Surgeons of the State of Washington. He first described the Medical Aid Act of 1917, as follows:

"This Act provided that the cost of the medical and surgical treatment should be paid for equally by the employer and employee. Two types of treatment were authorized, generally known as the 'State Plan,' and the 'Contract Plan' of treatment. Where the 'State Plan' operates, the employee and employer pay their joint fee to the State, which in turn pays the doctors for services rendered the injured workmen. Where the 'Contract Plan' operates it is provided that upon the consent of a majority of the employees and employer, a contract for the care of injured workmen can be executed with any physician or hospital association for a period not to exceed three years. However, the supervisor of the Industrial Insurance Division is required to investigate fitness and ability of the surgeon or hospital association to render satisfactory service prior to this arrangement becoming effective.

"The policy of the legislature to exact an unusually high professional standard from those engaged in contract practice is seen by the provision of the Medical Aid Law, permitting cancellation of these arrangements where unsatisfactory treatment is rendered the injured workmen, and the carte blanche authority of the Supervisor of Industrial Insurance to transfer an injured workman elsewhere for treatment where he deems it advisable so to do.

"During the past few years there has been a very noticeable trend towards the contract form of treatment by workmen and employers who had previously operated under the 'State

Plan' The workmen and employers have observed with alarm and suspicion the increasing medical aid contributions required of them These rates have increased from 100 to 300 per cent during the thirteen years of operation under the 'State Plan' and their joint contributions from 1917 to 1929 when the last figures were available, was the astounding sum of $7 800 000 00 which sum was required for hospital and medical care of injured workmen, while the total amount paid for compensation to the injured workmen since the creation of the Act in 1911 to 1929 was only $48,000,000 00, a truly disproportionate ratio So the workmen and employer have taken counsel in the matter in an effort to correct the above seeming discrepancy, and for a remedy have turned to the 'Contract Medical Plan' as permitted by the law, in order to avail themselves of a more specialized and economic service

"Under the 'Contract Plan' of treatment the average time loss per claim filed in 1929 was 34 days, as against 40 days per claim under the 'State Plan' It is obvious that the worker lost six days in wages, and the State paid six additional days compensation on State claims in these two industries Nor were the results as to permanent partial disabilities any more favorable under the 'State Plan' The records show that the degree ratings on permanent partial disability awards cost $60 per claim more under the 'State Plan,' as against the contract medical service The figures just quoted indicate that the injured workmen under the 'Contract Plan' received wholesome medical treatment by reason of their speedier recovery, with a lower time loss, and are returned to their work with a lesser functional disability

'It is further charged by the Chairman of the Public and Industrial Relations Committee of the King County Medical Society that 'under the contract plan, a leg may be amputated to save the hospital expense incident through effort to save the leg This allegation is wholly without foundation and persons making such charges are either misinformed or they are deliberately misstating the facts

"The records prove that for the year 1929, with three times the number of cases treated as against the year 1912 (when the 'State Plan was at its height), the ratio on amputations to claims adjusted was 400 per cent lower

"Surgeons following the contract plan of treatment do not desire to abolish the state plan of treatment They believe that the workmen and employer should be allowed to choose

**FOR
CONVALESCENT DIET
IN WINTER EPIDEMICS**

BEMAX

REG U S PAT OFF

ENTIRE CEREAL-EMBRYO

CONVALESCENCE following prevalent winter diseases of the respiratory tract may be materially aided by improvement of the diet through addition of BEMAX

BEMAX is entire cereal embryo, so processed as to retain richly vitamins B_1 and B in highly concentrated form

This delicious food is extremely rich in vitamin B — perhaps the richest known source, its concentration permits measured quantities without bulk or roughage, and its palatability makes it eagerly acceptable to the most delicate cases

Try BEMAX yourself—regularly for at least a month! A tablespoonful on cereals, cooked fruits, or in milk adds valuable vitamin B to your diet Improvement in nourishment by correcting Vitamin B deficiency may result in better tone, increased appetite, and an improved bowel function

the form under which they consider it most favorable to operate."

The statement against contract practice was prepared by Dr. H. J. Davidson, of Seattle and may be summarized as follows:

"Early in 1930 King County Medical Society ordered fact finding investigation and initiation of effort to correct certain conditions which were known to have progressed to the point of having become public health problems.

"Official action of the medical society limited the activities of the committee to three specific problems:

"1. Certain contracts under the Medical Aid Law.

"2. Certain so-called medical contracts executed by doctors contracting under the Medical Aid Law.

"3. Commercial solicitation of professional business, particularly to secure the above contracts either by physicians themselves or by lay agents hired directly or through corporate agencies.

"The Medical Aid Law has been in operation thirteen years. Conceived in altruism toward the workmen to ease the financial burden incident to the surgical care of injuries, it has made possible the exploitation of medical aid fund by contract doctors for profit to the possible tragic detriment of the injured, a condition contrary to good financial and good public health policy.

"The Law legalizes contracts and provides that the employer and employees in conference may choose the contract alternative. It does not provide nor does it specifically prohibit, nor was it the intent of the law that doctors should take the initiative, go themselves or send their hired lay representative to employers and groups of employees to solicit the contracts as they have done and are now doing.

"Under the terms of the contracts as executed by contract doctors, ten cents on the dollar of the medical aid trust fund goes to the state for administrative expense; ninety cents on the dollar, at the time of collection from labor and industry, is turned over to the contract doctor. He is custodian of the fund: he administers it, determining what service shall be rendered, including his own professional services, hospital, nurses, drugs, appliances and even professional consultants. He disburses for all services and keeps as his own the unexpended portion. Therein lies the censurable financial policy, and therefrom arise

(*Continued on page 255—adv. xvii*)

(Continued from page 254—adv. xvi)

the possibilities of detriment to public health.

"In exploiting financial possibilities for personal gain under the law, contract doctors sometimes reduce services to injured workers to the point of inadequacy and incompetence. Under their administration of the fund, limbs may be amputated to save the hospital expense incident to effort to save them, and workmen with fractures and serious internal injuries may be allowed to succumb without effort to determine and treat the internal injuries because of the hospital expense entailed during repair of the fractures in case the life is saved. They hire laymen to solicit the contracts, thereby diverting a considerable portion of the fund to channels of commercialism, and, as a corollary to the medical aid law contracts, contract doctors are carrying on a wildcat health insurance business. They are known to have paid up to 20 per cent of the gross revenue derived from the contract and up to $600 a month to lay agents, through whom the contracts were secured. Through the use of hired lay agents they secure contracts remote from their home towns, then sublet to local doctors for 25 per cent of the total revenue, their sole service being to secure and to sublet the contract; or they hire the cheapest available local doctor to render service under the remote contracts and often require him to pay them 50 per cent of the gross revenue derived from all private practice developed while in their employ.

"The group of workmen included under the medical aid law contracts comprise convenient groups to bring into the wildcat health insurance activities. For from seventy-five cents to one dollar and fifty cents a month, contract doctors agree to render all professional services and pay all costs incident to the care of accidents not included under the medical aid law and all sicknesses with specific limited exceptions. This contract is a limited health and accident insurance policy with all the evil possibilities of wildcat insurance, to wit:

"1. The contract doctor is the insurer.

"2. The insurer is unsupervised as to financial resources, and as to performance under his contract.

"3. He determines the rates, administers the insurance fund, determines what services shall be rendered, renders that service personally or through agents in his hire, and retains the unexpended portion.

"Any insurance actuary will testify to the fact the rate is utterly inadequate. Every man operating would go bankrupt in a short time, if he fulfilled the terms of the contract. Any un-

Mead's Powdered Lactic Acid Milk No. 1 (containing Dex-tri-Maltose) may be boiled for experiments without curdling. While boiling is unnecessary, as the product is practically sterile, it is a feature which removes a hindrance to the physician's technique confronting him in the use of the old type of powdered lactic acid milk which cannot be boiled without curdling. This product never curdles; it is always ready, and quickly reliquefied. No ice is necessary to keep the powder; it is convenient while traveling. Samples and literature sent on request. Mead Johnson and Company, Evansville, Indiana, U. S. A.

(*Continued from page 255—adv xvii*)

prejudiced physician will testify to instances of failure of the insurer to fulfill his contract.

"A man with a perforating ulcer of the duodenum went nine times to the contract doctor. The eighth and ninth times he was so ill his son had to take him after refusal of the contract doctor to call at the home. No adequate history was obtained, absolutely no examination was made. He was given a box of pills, some ten cents in value, which proved so laxative that their use had to be discontinued. He then consulted his family physician who rendered proper service, including hospitalization and operation, incurring some $400 expense. The contract doctor willfully and negligently evaded financial obligation, the professional responsibility and effort, to save for himself the cost of hospitalization and special nurses.

"The ideals and ethics of the medical profession have through all time paralleled very closely those of the legal profession. The Legal Practice Act of the State of Washington specifically prohibits the use of hired lay solicitors for securing professional work for lawyers. It is declared to be against public policy. The Medical Practice Act does not contain any similar clause, although seventeen states and territories do have laws prohibiting the practice, with revocation of license as the penalty.

"To remedy the situation we propose:

"1. An amendment to the present Medical Aid Law, providing that the doctor shall receive or have an interest only in that portion of the fund which he earns through personal professional service.

"2. An amendment to the insurance code bringing the supplemental medical contracts under the jurisdiction and supervision of the Insurance Department.

"3. An amendment to the Medical Pratice Act making it unlawful for doctors to solicit professional business.

"The critical activity of the medical profession is not directed against industrial medicine as developed by such companies as the Pacific Coast Coal Company, the Puget Sound Light and Power, and the Northwest Improvement Company. Under their system the fund is administered conjointly by the company; and employees and individual cases are sent to doctors competent to treat the particular ailment, while the doctor has financial interest in only what he receives for his personal services. We recommend that provision for that type of service be retained."

PROGRAMS OF ANNUAL MEETINGS IN GEORGIA

The January issue of the Journal of the Medical Association of Georgia contains the following editorial plea for contributions of scientific papers for the annual meeting:

"The criterion by which a medical meeting is ultimately judged is its scientific program. We do not under-rate the enhancement of good will which comes naturally out of our annual gatherings. When one tries to see the worthy qualities which abound in his neighbor,

(*Continued on page 257—adv. xiv*)

(Continued from page 256—adv. xviii)

or his medical colleague, these are usually found sufficient to erase any cause for misunderstanding and to furnish a sound basis on which mutual friendship may be built. If therefore, one attended regularly the annual assembly of our Society for no other reason than that he might mingle with the rank and file of its membership, he would be amply paid. Nor should entertainment in the form of open house parties, banquets, golf, trapshooting and the like, be given a dominant place when the assembly's program is planned Such natural expressions of Southern birth and tradition will continue to express the pride and pleasure felt by the host society when it is honored by a paternal visit in its home city. Moreover, the building of good fellowship and the program of entertainment must be looked upon as the adornment which, by design, augments the scientific appetite—lest we go away from a repast whose caloric value will be found inadequate to prepare us for the strenuous problems of every-day practice. We want a program then, with the customary embellishments, but let us also have more meat; and since the mental attitude of the diner predetermines his ability to take lustily of the bill of fare, the Committee on Scientific Work urges that you point especially for the meat course in the approaching session in Atlanta and that you come with your appetite for scientific and clinical medicine so well whetted that you will stay by the program from soup to nuts.

"But how shall we eat if we have no meat—meat that represents the viewpoint and experience in clinical medicine of the various districts of our great state? For years the Committee on Program has issued its appeal for papers to the whole membership, to have a response only from the centers of population with here and there a representative of our smaller cities and rural communities. Our program, to pursue the simile further, represents a 'state products' dinner and should be contributed to from all parts of the commonwealth. We want the viewpoint of the doctor who digs deeply into the truths of the science of medicine but there is room for good old-fashioned clinical medicine such as grows out of the experience of the practitioner somewhat removed from the atmosphere of scientific debate.

"With these thoughts in view your Committee at a recent meeting authorized the publication of this appeal. You are requested to mail titles for papers to the secretary, Dr. A. H. Bunce, not later than March 15, 1931, at which time the program will be made up. We want it to be, in fact, a state wide product."

Puretest Mineral Oil

THE RATIONAL TREATMENT FOR AUTO-INTOXICATION

RECENT clinical research has shown that Puretest Mineral Oil absorbs and removes the products of protein decomposition (indol, skatol, histamine) which cause the headaches, lassitude, depression and associated disturbance commonly known as auto-intoxication resulting from constipation.

These conditions in your patient will respond to treatment with Puretest Mineral Oil.

Puretest Mineral Oil is crystal clear, brilliantly transparent and entirely free from odor and taste. It is of very high viscosity and has a uniformly high specific gravity, (.885 to .895 at 25° c). The high viscosity and specific gravity assure a maximum of penetration and softening effect as well as a maximum of lubricating action.

The great advantage of Puretest Mineral Oil over other laxatives is that the intestinal toxins are absorbed into the oil and not into the system. It is anthracene-free and absolutely non-irritant.

Puretest Mineral Oil and all other Puretest products are obtainable at all Liggett and Rexall Drug Stores.

Physicians are invited to visit the Pharmaceutical Departments of these stores, or write us for samples for analysis and clinical test.

CARE OF THE POOR BY MEDICAL SOCIETIES, A MICHIGAN OPINION

The January issue of the Journal of the Michigan State Medical Society has the following editorial discussion of the Iowa plan by which county medical societies treat the indigent at public expense:

"Once a year state secretaries and editors of State Medical Journals respond to a call to the headquarters of the American Medical Association, where they meet in a two day convention. What do they discuss? Nothing in the field of scientific medicine or surgery. The subjects that engage their attention belong rather to the social and economic phases of medicine, such as the care of the indigent sick, health insurance or medical publicity.

"There is a strong feeling that in the care of the indigent sick the medical profession is doing more than its share. The problem is not the concern of the medical profession alone; it is a community problem. As the situation is at present, provision is made in most communities to meet the expenses of every factor concerned except paying the doctor, who is expected to contribute his services, in most instances without any remuneration whatsoever.

"Among the plans proposed for the care of the indigent sick is a blanket contract scheme which has been tried out in eleven counties in Iowa for periods ranging from twenty-six years to one year. The County Medical Society enters into an agreement with the supervisors of the county to provide medical and surgical care to indigents for a fixed annual sum. This sum is paid over to the County Medical Society and is divided among its members, all of whom, some time during the year, have served in a rotating service. Details of the contract plan may be obtained from the County Medical Society at Des Moines, Iowa.

"Membership in the various county societies in Iowa which have adopted the blanket contract with the county ranges from ten to eighty-six. We presume the number of physicians indicates in a general way the density of population. The distribution of funds for the medical care of the poor ranges from $1,600 to the county having the ten physicians to $12,600 in the county with eighty-six doctors.

"The sum paid into the treasury of the county medical societies takes care of the expenses of the society, including medical protective insurance and fees for providing scientific programs and such other items as are ordinarily met by membership fees. The distribution of remuneration

(*Continued on page 259—adv. xxi*)

(*Continued from page 258—adv. xx*)

to members is made after deducting such incidental expenses as we have mentioned

"This plan should not be lightly dismissed by county societies of Michigan without serious consideration. Enabling legislation may be necessary before a Michigan County Medical Society can enter upon such a contract. The plan has been tried and proven successful in the smaller municipalities How it would work in the larger centers of population remains to be seen"

WOMAN'S AUXILIARY CONTEST IN KENTUCKY

The Woman's Auxiliary is popular in many States, and many State Journals conduct departments on their activities. The Kentucky Medical Journal for January contains an outline of a contest between the county auxiliaries. The contest is in twelve parts to each of which from twenty to five hundred points are assigned. The winner will be the Society earning the greatest number of points per capita; and this figure will be the total number of points earned by the society, divided by the number of its members. The parts of the contest are as follows:

1. For each paid-up member, 30 points.

2. For each subscription to *Hygeia,* 20 points.

3. For each biography of a physician born or practicing in the county, 25 points.

4. For each story of medical practice, superstition, or other interesting data, 20 points.

5. For each dollar secured for the Jane Todd Crawford Fund, 50 points Mrs. Crawford was the patient on whom Dr. Ephraim McDowell performed the first ovariotomy on December 13, 1809, in Donville, Kentucky.

6 For each Auxiliary scrapbook brought to the annual meeting, 50 points.

7. For each article for the State scrapbook, 20 points.

8. For each monthly contribution of Auxiliary news to the Kentucky Medical Journal, 20 points.

9. For each regular meeting held, 50 points.

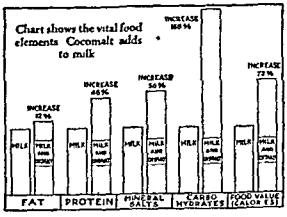
10. For each study course of nine health lessons, 500 points

11. For completing four or more lessons sent out by the A.M.A. Auxiliary, 200 points

12 For each member attending the annual meeting, 25 points.

When convalescents demur at the monotony of milk

Cocomalt not only renders it more palatable, but increases the food value over 70%



COCOMALT is a balanced combination of milk protein, milk minerals, converted cocoa, sugar, malt and eggs —to be added to milk, hot or cold. So mixed, the result is a delicious, chocolate flavor food drink—high in nutritive value and extremely palatable to convalescents, children and invalids.

Cocomalt contains Vitamin A and also Vitamin B complex. Moreover, it contains Vitamin D in sufficient quantity to make a definite contribution to the antirachitic potency of the diet.

Cocomalt is made under modern, sanitary conditions —packed in air-tight tin containers. Sold at grocery and drug stores. ½ lb., 1 lb., hospital 5 lb. can.

HEALTH BUREAU OF CAPE COD

The editorial department of the November 27th issue of the *New England Journal of Medicine* contains the following report of the meeting of the Health Bureau of Cape Cod:

"The fall meeting of the Cape Cod Health Bureau was held in Hyannis on November 19. Anti-mosquito work, the Cape as a tuberculin-tested area, and standardization of the regulations of boards of health received especial consideration. The President, Mr. G. W. Hallett of the Barnstable Board of Health, in his opening remarks referred to the system of health units, the formation of which is of such vital interest to the State Department of Public Health.

"With reference to mosquito elimination Dr. A. P. Goff, County Health Officer said that $75,000 had been available for the work on the Cape this year. About one-third of this amount was spent in ditching, now practically half completed, and the other two-thirds was spent on local work. Various localities report a great diminution in the mosquito pest and it is expected that many other areas will be practically mosquito-free next year.

"In his regular report Dr. Goff presented some statistics with respect to the diminution of disease and noted that the State is making a special endeavor to secure the earlier reporting of venereal diseases. The earlier diagnosis of tuberculosis is also receiving the attention of the Bureau and an effort is being made to interest physicians in that problem.

"At the afternoon session Mr. J. T. Mecarta, County Milk Inspector, reported two convictions for the violation of the cattle quarantine in introducing non-accredited cows into Barnstable County.

"The rest of the session was devoted to a discussion of the uniform regulations for health boards, with the usual careful consideration of practical details which characterizes these meetings.

"For its final action the association voted that a committee on regulations be appointed to confer with the joint committee of the Massachusetts Association of Boards of Health and the State Department of Public Health."

TUMOR CLINICS IN PENNSYLVANIA

The January issue of the *Pennsylvania Medical Journal* describes one phase of its work of cancer prevention as follows:

"In the furtherance of its plan for the installation of Tumor Clinics throughout the State, our Cancer Commission recently requested Jefferson Medical College and Hospital to conduct a Tumor Clinic Day for those especially interested in the organization of tumor clinics. The all-day tumor clinic and demonstration held at the above-named hospital, in Philadelphia, on December 12, was, in the following words of President Ross V. Patterson a great success: 'There were over one hundred in attendance, and they came from every quarter of the State. Chairman Wainwright was much pleased. I really feel that the Cancer program has gotten a splendid impetus for the coming year in the gathering here in Philadelphia.'

"It is hoped that many general hospitals throughout the State will develop tumor clinics along the lines advanced by the Cancer Commission, and that Pennsylvania may soon equal the record credited to the State of Massachusetts by the Committee on the Costs of Medical Care in the following words: 'Over eighty per cent of the people in the State (Mass.) who have cancer, it is estimated, have been seen by physicians. For every cancer patient visiting one of the eighteen state clinics, twenty-two visit a physician's office.'"

NEW YORK STATE JOURNAL of MEDICINE

AN EVALUATION OF THE NEWER METHODS OF TREATING SYPHILIS:*

(Clinical Features)

By MIHRAN B. PAROUNAGIAN, M.D., NEW YORK, N. Y.

IT is with much pleasure that I present to you a semi-historical and fully clinical review of experiences in treating syphilities for the past thirty or more years Yet, contact with students, and internes as well as recent graduates who are all interested in syphilology, convinces me that a review such as this should prove of value. Oftentimes, new procedures and new remedies make us forget the old and when specifics are offered, nearly every vestige of previous clinical experience is forgotten.

In no other field than syphilis does this last hold so true. Someone has said that if a physician forgets nearly everything else, he remembers chrysarobin for psoriasis. But even the physician who can not recall chrysarobin, remembers salvarsan. May I carry you back to the pre-salvarsan era?

Treatment of syphilis prior to 1910 or thereabouts had remained unchanged for practically four hundred years. The accidental finding, for accident it must have been, that the use of mercury by inunction, by inhalation, by oral administration and then by intramuscular, and finally intravenous routes led to a schedule of therapy which was varied only by the caprices of the administrator and the steadiness of the patient.

The first reference which we find to mercury as a remedy for syphilis occurs in the immortal poem of Hieronymus Fracastor, to whom, indeed, we are indebted for the first accurate description of the clinical phases of syphilis, and who has given to us the name of the disease. In the prose translation of this fifteenth-century masterpiece we find the following interesting paragraph:

"At the beginning, mercury was employed associated with lard; later it was combined with the turpentine of Epirus and with the resin of the majestic birch. Certain physicians today combined it with horse fat or bear's grease, or bdellium, and with the juice of cedar; others with myrrh, with male incense, with mibium, and with burning sulphur. For my part, I prefer to alloy it with a mixture of black hellebore, orisroot, galbanum, asafetida, and oil of mastic and oil of native sulphur. Patients, a truce to the disgust which may be caused by this remedy. For if it is disgusting, the disease is still more so. Besides, your cure is at this price. So, without hesitation, spread this mixture on your body and cover with it your entire skin, with the exception of the head and of the precordial region. Then, carefully wrap yourself in wool and tow; then get into bed, load yourself with bed covering, and thus await until a sweat bathes your limbs with an impure dew. Ten days in succession renew this treatment, for ten entire days you are to undergo this cruel trial whose beneficial effect will not cause you to wait."

Here, one has the expounding of a treatment which, with slight modification, had come down to us through almost four centuries as an ideal method of combating syphilis. Besides recommending mercury as an inunction, Fracastor also recommended its use by method of fumigation or inhalation. This method, as you know, enjoyed excellent repute up to the middle of the last century.

It was but natural that early excellent results of mercurial treatment in this form should have been followed by its use internally in the form of pills and in combination as mercury salts. The internal administration of mercury had been perhaps the most commonly accepted form of treatment in the last century, and indeed Sir Jonathan Hutchinson, maintained its supremacy over all other methods

In the last quarter of the nineteenth century, mercury was employed in France in the form of injection; here, also, as in the internal administration, the various salts had been lauded

*Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1930.

one above the other. In the opinion of the most eminent syphilographers of that day, the insoluble salts were capable of controlling the disease with far greater ease, with less personal inconvenience to the patient, and with less personal care on the part of the physician than the soluble salts. Employed daily the soluble salts of mercury were held to be the most efficacious but there were few patients who were able to stand the financial strain in that day of private practice, not to mention the loss of time and discomfort.

I cannot pass from the history of mercurial treatment without alluding to the inhalation method of treatment, which at certain spas enjoyed excellent repute. While good results were obtained, the method did not commend itself on account of its impracticability. The method of inunction, however, differed but little from the inhalation method, for it had been conclusively shown by investigators that the chief benefit derived from this method lay in the volatilization of the mercury and its subsequent absorption into the lungs, very little if any mercury being absorbed through the skin itself. The chief objection to this method lay in the fact that, one could not estimate the dose, and the undeniable fact that stomatitis was far more common than with other methods. However, it was an efficient and at times the most practicable form of administration.

I close this section on the use of mercury in the olden days by this quotation from, J. William White, writing on the Treatment of Syphilis, in Morrow's System:

". . . . the essential point in the treatment of syphilis is the administration, during a sufficiently long period of the largest dose of mercury which can be taken and absorbed without prejudice to the general health."

I will not bore you with the list of drugs used in the adjuvant treatment of syphilis. You all recall the iodides we ordered, either by drop method or as mixed treatment. Our prosperous patients left us periodically to get boiled out at one or another of the Hot Springs in this country or Europe.

Looking backward with calmness to our results with mercury, can we say that we cured patients with undoubted syphilis in those days? We admit that symptoms were controlled, but a large proportion of late recurrences which came under our observation had been treated early in the disease with the mercurial popular at the moment.

Most of you among my colleagues remember with what acclaim the medical and lay world was startled by the discovery of a new and powerful chemical remedy for syphilis. Thanks to the untiring efforts of the late Professor Ehrlich and his co-workers, arsphenamin and neoarsphenamin were offered as the possible means of eradicating or at least controlling syphilis with a single treatment. At first, it was hoped that the remedy was entirely specfiic, that is, that its single application sufficed to eradicate the disease for all times. Beautiful in theory, the fact was sadly admitted that such was not the case. The remedy readily controlled the symptoms of the disease, but a single injection seldom if ever eradicated it. We soon knew that arsphenamin, in order to effect a cure, must be repeated time after time. At first arsphenamin was injected intramuscularly in neutral suspension, into the buttocks or the muscles of the back between the scapulae; later in the form of oily emulsion, etc. On account of pain, sloughing and necrosis, as well as painful infiltrations remaining for months and years in some cases, this method was discarded for the intravenous method.

Few among you need be reminded of the changes in arsphenamin brought on by the World War, or of the alterations made in its composition by researches in our own country. As you know, we have the old, neo- and silver-arsphenamin to select from in the choice of our most potent arsenical remedies to use in the treatment of syphilis.

Having used it from its introduction, I am one of those who have strongly favored the old arsphenamin in preference to neo. There is some difference of opinion on this point, some syphilologists believe that neo is just as efficacious as the old. The popularity of neo to my mind is due to its ease of preparation and administration. While I strongly favor the old arsphenamin wherever I can, I use discretion in the selection of the particular variety. In pregnant women, children, in patients with advanced degenerative nerve conditions, aneurisms, and those with extensive cardiac and renal lesions, I give preference to neo.

Deprived of proper facilities for treatment of neuro-syphilis on a larger scale with malaria inoculation or by artificial hyperpyrexia induced by electrical currents, I would use sliver or neo-silverarsphen, in preference to the others available in the arsphenamin group.

But, unconsciously we have come to modern times in the treatment of syphilis. Was mercury dropped because arsphenamin came to the fore? It was not. Programs of use of both mercury and arsphenamin were proposed and followed. The patients were given the opportunity of cure which arsphenamin held out, but were not denied the benefits following

the use of mercury. That arsphenamin was superior to mercury has never been questioned.

Not so many years ago another metal was advanced in the treatment of the syphilitic, namely bismuth. Heralded as superior to every other drug, bismuth has gradually fallen in favor so that it is battling for second place to arsphenamin and truth to tell, probably will come in a poor third.

At present, I have retained bismuth essentially for those patients who have become intolerant to arsphenamin and mercury. Most patients tolerate bismuth without difficulty.

The iodides are still used having regained popularity in the late manifestations of syphilis at least. The patient gets iodides by mouth or by injection intravenously. Despite the ease, and rapidity of absorption of iodide on oral administration, it is my clinical judgment that the intravenous route offers advantages not to be disregarded.

Let us examine our results with arsphenamin and its various modifications. The newer remedies cause a more rapid disappearance of active infectious lesions which result in reduction of period of danger to the family, and public at large.

It was not unusual to have a patient exhibit an ulcerated throat for many months despite mercurials and all sorts of local applications in the olden days; with the advent of arsenicals, in a few days these symptoms readily disappear.

Since the main hope for permanent cure of syphilis depends on early sterilization of the blood, the newer remedies offer the best means of cure which mercury could not effect.

The expectant mother with syphilis treated with the newer remedies has a fair chance of delivery of a living child, because of the quicker and surer destruction of the spirochetes. Congenital syphilis is not the hopeless task it was a generation ago.

Visceral syphilis is more amenable to the newer remedies than the old, and the danger to the patient in therapeutic attack has been diminished but not extinguished.

The bête noir of former years of syphilology, namely neuro-syphilis, particularly paresis is not beyond relief with the newer treatment of hyperpyrexia induced by malaria or by electrical means. Shock treatment with foreign proteins offer a substitute for the other methods if they are feasible.

My experience with unquestioned instances of reinfection has been a broad one. Many of those who objected to official recognition of this possibility have been convinced of it. Yet, reinfection was a rarity in the pre-arsphenamin period. It seems to me that patients whom I observed throughout one sequence of syphilis and who remained with me for their courses of arsphenamin and mercury, with gradual reversal of the serology and who subsequently reappeared with definite syphilitic chancre at sites distant from the draining area of the first chancre must be regarded as reinfection. I have from time to time, had such patients before the various societies devoted to dermatology and syphilology and the histories have been recorded in our official journal.

Let us draw a balance between the old and the new. I would have you consider for a moment how you would react therapeutically, if you were deprived of the newer remedies in treating syphilis. Would you be content to depend on the mercurials to which we were limited prior to 1910?

SUMMARY

After experiences extending over twenty years with arsphenamin, its modifications, and substitutions, I have arrived at a number of distinctions as to the best use of the most popular.

Arsphenamin, is the drug of choice in early syphilis, chancre and secondaries among the young patients, robust and otherwise in good physical condition.

Neo-arsphenamin, I prefer in elderly people, pregnant women, children, persons with kidney, cardiac and other complications.

Silver-arsphenamin, quite valuable in neurosyphilis, extensive gummatous ulcerations, in anæmic subjects and for those who do not tolerate other arsenicals. I favor this preparation for provocative Wassermann test.

Mercury, is always included in therapeutic attack on syphilis, although the reaction of the patient decides the type, dosage and period of use.

Bismuth, is substituted for mercury, if the latter is not tolerated, and also when the patient is sensitized to both arsphenamin and mercury. I have at times noticed some pleasing clinical improvement with the use of colloidal bismuth in congenital syphilitics and tabetics.

Iodides, are employed in all types of infiltrating lesions, such as remains of chancre, deep-seated secondaries and gummous deposits.

The acceptance of re-infection of syphilis in modern times of arsphenamin treatment seems to me to be the best indication that the newer methods are more successful than previously, when reinfection was rarely if ever accepted as possible when and if the first infection of syphilis was beyond reproach.

A MODIFICATION OF THE DOUBLE CIRCLE OPERATION FOR PENDULOUS BREASTS

By CLIFFORD F. DOWKONTT, M. D., NEW YORK, N. Y.

THE condition described as pendulous breasts is an extremely common one, and one which causes women much suffering, both physical and psychical.

Among the physical discomforts of large prolapsed breasts may be mentioned the following: pain and dragging sensations in the neck and shoulders as well as in the breasts; interference with respiration and the free movement of arms and body; maceration, inflammation and eczema of the skin caused by cutaneous friction and an unsightly disfigurement of the normal bodily contour. In order to hide this disfigurement women resort to such practices as a stooped posture or bandaging the breasts tightly to the abdomen.

Psychically, the changes vary from embarrassment and feelings of inferiority to actual psychotic reactions with suicidal tendencies, as in a case reported by Kausch.[1]

Economically, actresses, singers and dancers, whose earning capacity depends almost to as great an extent upon their appearance before a critical audience as upon their talent, are put at an enormous disadvantage by this condition which in many instances may be the cause of absolute vocational failure. In private life the economic disadvantage is less obvious; but it is easy to understand that a sensitive business woman, or one who has to appear in public in any capacity, would suffer from the abnormality and ugliness of enormous pendulous breasts.

On December 4th, 1929, the author[2] reported a series of ten cases of pendulous breasts successfully operated upon by means of a technique which involved the use of two circular incisions, the removal of the skin and adipose tissue between them, and the suturing of the two incisions to each other, leaving a linear scar completely encircling the breast. It was pointed out that although the scar was reduced to a minimum by a special suturing technique, that part of it which extended around the upper half of the base of the breast was an undeniable disadvantage. Accordingly the author devised a modification of the two circular incisions, changing the circles to semicircles and placing all suture lines at the level of the nipple or below it; but retaining all other features of the original technique.

In considering the advantages of the modification of the original technique, it is apparent at once that the avoidance of any suture line in the upper half of the breast is a very important improvement. Costumes and evening gowns of extremely low-cut may be worn without hesitation or embarrassment by patients so operated upon. The social and economic advantages are obvious. Moreover by adherence to the original technique of firm suspension of the gland by the pectoral fascia flap, permanence of the results is assured. In addition there has been no sacrifice of contour, and exposure is sufficient to allow the safe excision of excess glandular tissue if present.

It has been the author's practice to excise completely whatever breast tissue may lie peripheral to the normal border of the gland. This procedure leaves behind no islands of gland tissue, undrained by ducts, to give rise to trouble during lactation. The dissection near the areolar border is carried out in a direction away from the nipple. The ampullae and main ducts therefore are safe from injury.

To a superficial observer this operation might seem quite formidable. From the surgeon's standpoint the technique is certainly intricate and involved and requires the use of some 150 interrupted sutures. However, the complete operation on both sides is now performed by the author in an hour and a half to two hours, depending on the degree of prolapse present. A very satisfactory anesthesia is obtained by using nitrous oxide-oxygen together with small amounts of ether (3 or 4 ounces for the entire operation). This causes slight discomfort to the patient. There is surprisingly little post-operative pain, and the patient's chief complaint is the boredom of a week's confinement in bed.

Summary and Conclusions

1—Operations for pendulous breasts must recognize the importance of the following features:

a—Permanency of the results.
b—Scars which are not visible.
c—Contour approximately normal.
d—Equality of the two breasts in size and position.

2—The modified technique is based on the following principles:

a—Semi-circular skin incisions.
b—Under-mined semi-circular skin flap which forms the covering for the upper half of the breast.
c—Peripheral excision of excessive adipose and glandular tissue as in the original technique.
d—Pectoral fascia flap suspension of the gland.
e—Placing of all suture lines at the level of the nipple or below it.

2. Dowkontt, Clifford F.: An Operation for Pendulous Breasts. *Medical Journal and Record*, Dec. 4, 1929.

The following reports describe four illustrative cases in which the improved technique was used with results that were entirely satisfactory.

CASE 1

L. V., nullipara, aged 20 years, complained of large and pendulous breasts, a condition which had existed for 5 to 6 years. She stated that this deformity prevented her from obtaining employment in her profession,—that of an actress. Remainder of history negative.

On examination both breasts were found to be moderately pendulous and hypertrophied. See Figure 1. No tumor masses, no discharge from the nipples present.

A plastic operation on both breasts, including peripheral removal of excess glandular and adipose tissue, together with pectoral fascia flap suspension, was performed April 11, 1930. About 11 ounces of tissue were excised from each breast. Microscopically this tissue was that of normal non-lactating mammary gland.

Except for a slight intercurrent pharyngeal infection, the patient made an uneventful recovery and on April 21st was discharged from the hospital. Figure 2 shows the appearance of the breasts 6 weeks after operation. At that time the patient had already begun rehearsals and has since then been employed regularly on the stage in parts which require the wearing of extremely low-cut costumes. See Figures 3 and 4.

CLINICAL TYPES OF OCULAR PATHOLOGY DUE TO DISEASE OF THE PARANASAL SINUSES*

By LUTHER C. PETER, M.D., PHILADELPHIA, PA.

IN a paper read before the Pittsburgh Ophthalmological Society last January, I discussed "Determining Factors in the Ocular Complications of Nasal Sinus Disease." In that communication, I presented, first, the factors which lead to a difference in opinion as to the frequency of the occurrence of such complications; second, the anatomic factors which might be responsible for ocular involvement in sinus disease; and third, the pathologic evidence of such complications and the channels through which they are brought about.

The clinical evidence of this relation which I propose to discuss with you today as Part II is largely in the form of a lantern slide demonstration of types of cases which one encounters in an average practice. In 1921 in my presidential address before the Eye, Ear, Nose and Throat Section of the Pennsylvania State Society, I presented evidence of the cause and effect relationship of nasal sinus disease and obscure forms of uveitis and choroiditis. The facts offered at that time are up-to-date after the lapse of nine years. I can add nothing to that phase of ocular complication but increasing numbers of clinical cases to corroborate and substantiate the claims made at that time.

The other clinical evidence which I wish to present is that in which visual field studies are of outstanding value, in the form, first, of enlargement of the blind spot of Mariotte; second, retrobulbar neuritis; third, manifest optic neuritis, neuroretinitis, and papillitis; fourth, papilledema in all instances, unilateral or bilateral; fifth, chiasmal and tract disease; and finally, residual optic atrophy in a large number of cases.

Enlargement of the blind spot of Mariotte, the first group, is an almost constant symptom in sphenoid and posterior ethmoid disease. In acute involvement of the sphenoid, it is a most dependable sign, and in cases of posterior ethmoidal disease, it is rarely absent. (See Fig. 1.)

Retrobulbar neuritis is the second group. In the absence of visible fundus changes, this form of optic nerve disturbance is full of interest, and calls for skill in determining the correct etiologic factor in any given case. Some are inclined to believe that the usual cause for retrobulbar neuritis is to be found in multiple sclerosis. Conceding that many cases are due to this condition, it is a correct scientific attitude to maintain an open mind in each case, until the correct etiologic factor has been determined. If one's mind is closed to other causes, he is apt to be led astray and to fail in the proper diagnosis in many instances. Possibly it has been my good fortune to find spheno-ethmoidal disease as the cause of many cases of retrobulbar neuritis and multiple sclerosis a factor in comparatively rare instances. At all events, I have seen many cases which were promptly relieved by sinus surgery, and others, after late interference, less improved. When these cases are carefully studied with due regard for a logical sequence of events, the suspicion is strong in many instances, and the therapeutic remedy directed to the sinuses, medical or surgical, most convincing. A careful history will often elicit an admission of a "cold in the head."

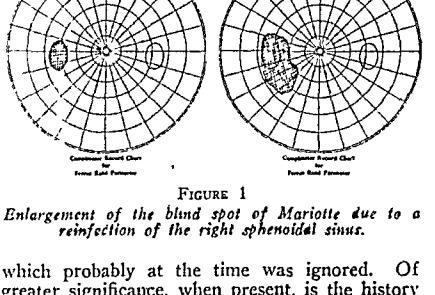

FIGURE 1

Enlargement of the blind spot of Mariotte due to a reinfection of the right sphenoidal sinus.

which probably at the time was ignored. Of greater significance, when present, is the history of fleeting attacks of visual disturbance, or more momentary loss of vision in one eye. This warning is present in many cases before a definite central scotoma can be demonstrated. In other instances, central blindness is sudden and at times complete, and restoration of vision most striking after prompt lavage of the sphenoid, with or without evidence of sphenoidal pathology. The channel through which this interesting condition is brought about is probably through the central vein of the retina. Whitnall calls attention to the fact that most of the orbital veins, which drain into the cavernous sinus, are wanting in valves, and because of this, reverse currents can be established. Furthermore, the same author stresses the comparatively small total caliber of the vessels which empty into the sinus, as compared with the caliber of the vessels coming from the orbit and nose to this sinus. This would lead to stasis, and even blocking of the venous circulation at times. Backing up of the current can in part explain some of these cases. That many cases of a retrobulbar character are largely toxic is evi-

*Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1930.

dent from the rapid recovery which one observes after lavage of the sphenoid or free establishment of drainage, either by surgical or medical means. (See Figure 2.)

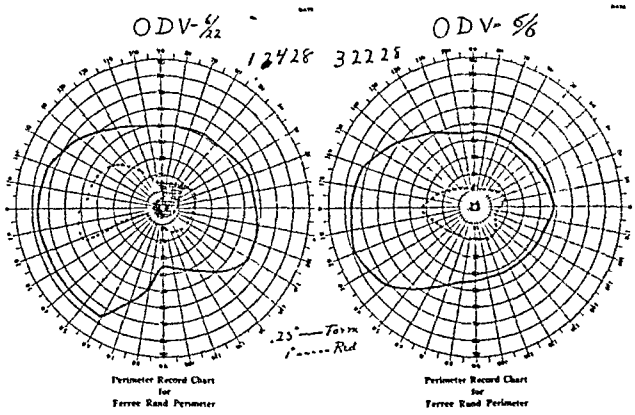

FIGURE 2

Retrobular neuritis with subsequent optic neuritis and residual atrophy.

In some instances, cases which begin as retrobulbar toxemia, if unrelieved, show evidence of inflammation in the form of optic neuritis, neuroretinitis, or papillitis, the third group of optic nerve lesions which may be considered together. These forms of optic nerve involvement are probably observed more frequently than any other type. The patient usually is conscious of central visual disturbance. Fundus changes are visible at a very early period in the inflammation, and if untreated, increase in intensity from simple blurring of the disc, venous engorgement with tortuosity, to a well-marked neuroretinitis and in aggravated form, a papillitis. The latter condition should be carefully distinguished from the next form to be discussed, namely, papilledema. (See Figures 3 and 4.)

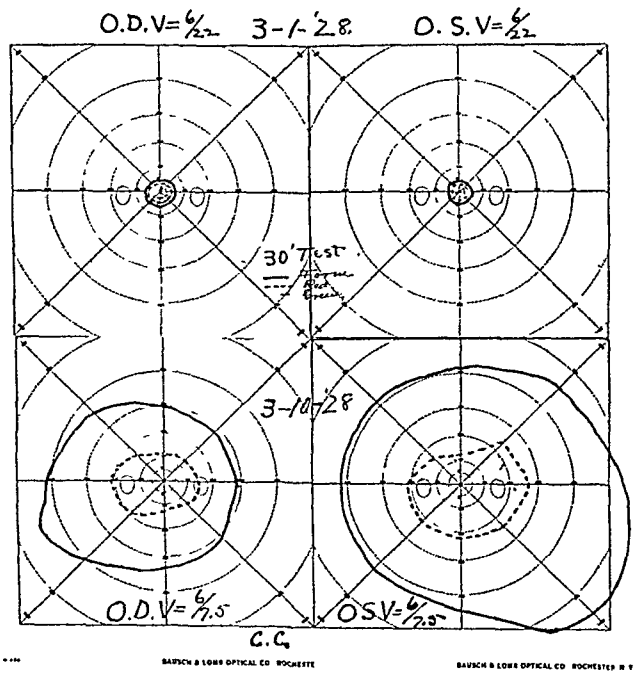

FIGURE 3

Bilateral optic neuritis due to bilateral sphenoiditis.

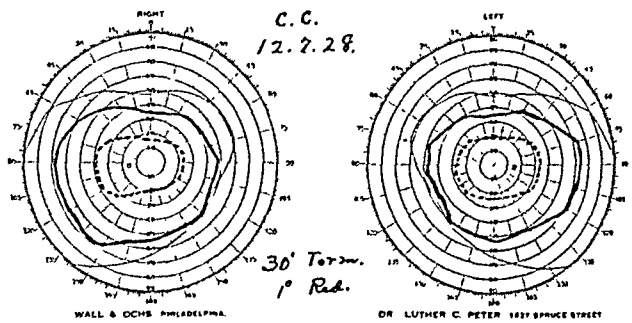

FIGURE 4

Complete recovery of Case No. 3, Figure 3.

This third group, like the one to follow, demands prompt attention on the part of the rhinologic surgeon if post-neuritic atrophy is to be averted. Field studies determine the progress from day to day, and if progressive loss is observed, prompt intra-nasal surgery is indicated. Judging from the many cases which have been under my observation, I am convinced that the degree of residual atrophy which will be present bears a direct relation to the length of time that is allowed to elapse between the onset of ocular disturbance and the incidence of surgery directed to relieve the sinus condition. The central scotoma of retrobulbar neuritis tends to disappear in most instances if properly treated, but unless the relief is prompt in optic neuritis, residual disturbance of vision with optic atrophy is the rule. (See Figure 5.)

Papilledema, the fourth group, is of unusual

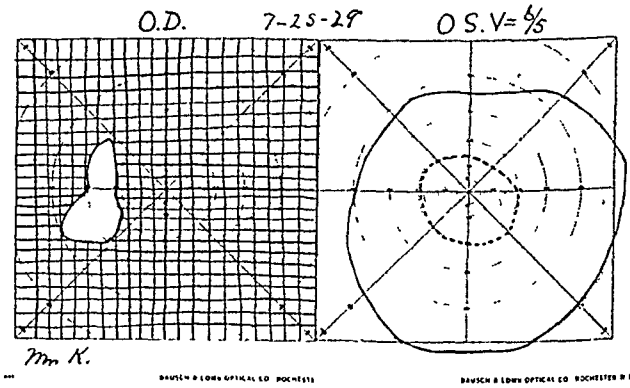

FIGURE 5

Neuroretinitis followed by postneuritis atrophy in O. D., due to a neglected sphenoiditis. In this case the patient had recurrent attacks of temporary amblyopia. Operation was performed too late ta prevent atrophy and blindness—a common type.

interest. Contrary to the belief of some, choked disc of varying degree is observed fairly often. It may be unilateral or bilateral. As pointed out in a former communication, the swollen nerve differs in two essential respects from the choked disc usually observed in increased intracranial pressure. There is more exudate present than is usually observed in the types of intracranial origin. The swelling sometimes assumes unusual proportions laterally and in elevation. Exudates are marked. It is, however, in the matter of recovery, in which the choked disc of this character differs from the usual form. After a decompression of the skull, the usual form of papilledema promptly subsides. In sinus disease, the elevation subsides slowly after sinus surgery, even though central vision improves and the peripheral fields are restored. This tendency of the discs to remain elevated for considerable periods is more or less general. Because of these peculiarities, I believe we should qualify choked disc of this type in order to call attention to its rather specific character. "Inflammatory choked disc" is open to criticism, but it is peculiarly applicable to the papilledema of sinus disease (See Figures 6, 7, 8, 9.)

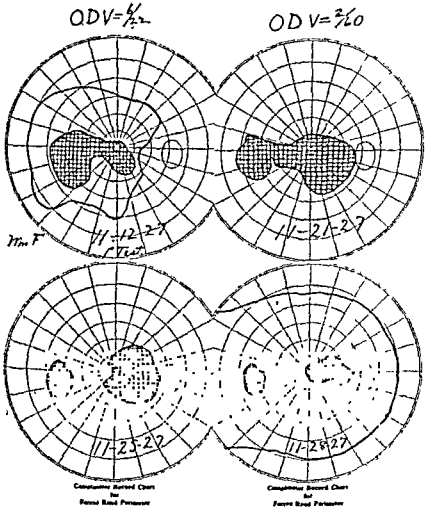

FIGURE 6

Monolateral papilledema due to acute sphenoiditis.

Chiasmal and tract complications may conveniently be included in one group. A glance at several of Schaeffer's dissections will do more than much discussion to convince the reader that sinus pathology may extend to these parts of the visual pathway. The following case is illustrative of a lesion which reached as far as the right tract. By a process of elimination and careful studies, a diagnosis of sinus disease was made. The fields show the subsequent course of events. This type is probably the rarest of the forms discussed. (See Figures 10 and 11.)

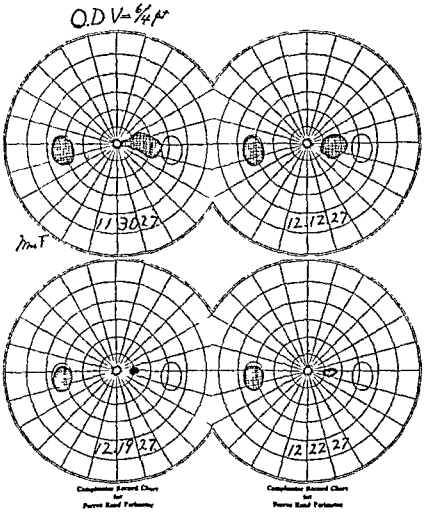

FIGURE 7

Same as Figure 6, but showing recovery after operation.

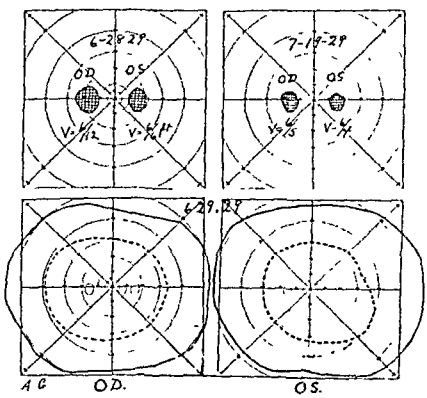

FIGURE 8

Bilateral papilledema due to chronic bilateral sphenoethmoiditis. Recovery after operation with persistence of swelling of the nerve heads for many months, but prompt recovery in the fields.

Any of the forms of optic nerve involvement but the first and probably the last may be followed by a postneuritic form of atrophy if operative interference is not practiced as soon as the etiologic factor is determined as sinus disease.

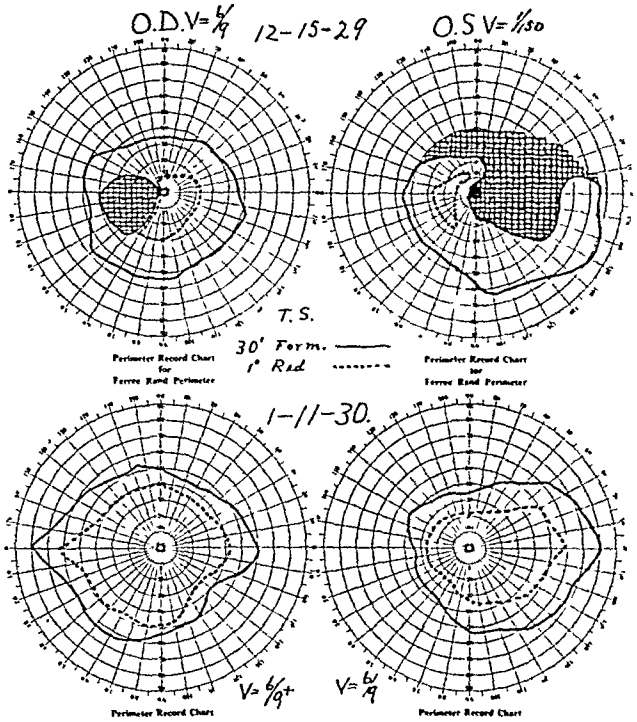

FIGURE 9

Fields in the same case following operation. Papilledema improved, but later was increased. Subsequently this case developed an abscess of the left frontal lobe of the brain.

In fact, experience teaches one that under certain conditions, exploratory surgery is justified without frank evidence of sinus pathology. These conditions are, first, a sequence of events which direct attention to the sinuses, e.g., the history of a nasal cold, followed at intervals by fleeting attacks of monolateral amblyopia; second, the exclusion of all other possible causes by a process of elimination. I have repeatedly requested exploratory surgery under such conditions, when rhinologic signs were too meagre upon which to warrant nasal surgery. The results in a majority of instances were most gratifying. The procedure is justified on the ground that the risk of an exploratory operation upon the patient is less if the sinuses prove to be negative, than is the risk of atrophy in a failure to remove operable pathology.

My plea to the rhinologist, therefore, is to operate when the ophthalmologist, upon proper study of a given case, makes the request.

Although the ocular muscles are not as often exposed to sinus pathology as are the uveal tract, the retina and the optic nerve, the motility of the eye is vulnerable and a sufficient number of cases are observed to keep one awake to disease of the sinuses as causative factors in functional and organic motor disturbances. My time is too limited to more than call your attention to the varying degrees of superior oblique disturbance, to ocular palsies especially of the internal rectus to varying grades and types of heterophoria, and to even profound proptosis, associated with ophthalmoplegia, when the orbit is invaded from spheno-

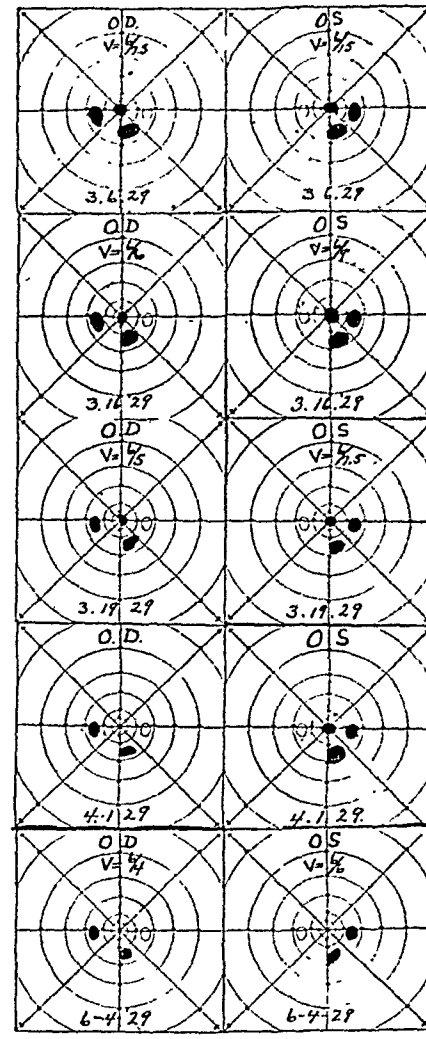

FIGURE 10

Bilateral retrobulbar neuritis with left homonymous hemianopic scotomas due to bilateral sphenoiditis, most marked on the right side. Recovery was prompt after operation; two small homonymous areas, however, remained as permanent defects.

ethmoidal disease, and in cavernous sinus thrombosis of nasal origin. The bizarre forms of motor disturbance, due to sinus disease, could well form the basis of a separate communication.

This discussion would fall short of completeness if I failed to call attention to a less frequent complication, but one which is concerned with the life or death of a patient when present—namely, cavernous sinus thrombosis of nasal ori-

gin. For a detailed report on cases of this character, those who are interested are referred to my communication in the Transactions of the College of Physicians of Philadelphia for 1929, and to the monograph by Eagleton on "Thrombophlebitis." At this time, let me but direct your attention to this most fascinating field in which prompt cooperation between rhinologist and ophthalmologist may save lives which otherwise are doomed to the usual results in this serious disease.

Discussion by Dr. Thomas H. Johnson, New York, N. Y.: Where there is pathology in the sinuses that can be demonstrated by *x*-ray or by the rhinologist, I think that operative interference in these cases is indicated, but I am not yet convinced that it is required in cases of optic nerve involvement where no pathology can be demonstrated. It is the common experience of men seeing brain tumor cases to have the patients

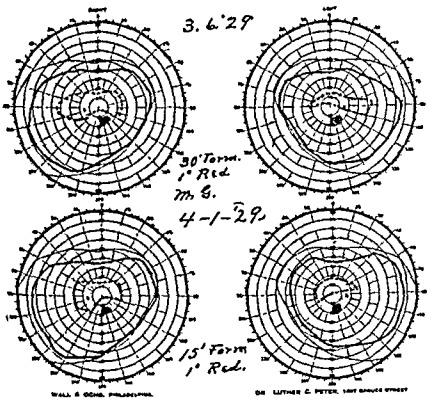

FIGURE 11
Peripheral fields in the same case—chiasmal and tract lesions.

give a history of having had various sinus operations upon the onset of eye symptoms which are so often the first to appear in brain tumor. I have under observation now two patients sent to the Neurological Institute as suspected brain tumors. One is a man and the other a woman and their history is very similar. Each had a rapid loss of vision in one eye. When I saw them each had a swollen optic nerve in one eye with a large central scotoma and vision reduced to hand movements. The fellow eye was normal In each case *x*-ray of the sinuses was normal and an experienced rhinologist did not find any pathology in the sinuses. Having the courage of my convictions I took the responsibility of not operating upon these cases. They were kept in the hospital for three or four weeks and a thorough study was made and no cause could be found for the optic nerve condition. I have observed these cases over a period of months and in the case of the man the swelling of the optic nerve head has entirely receded, the scotoma has disappeared and his vision has returned to normal. In the case of the woman the swelling of the nerve has receded entirely and there is only a blurring of the nasal disc margin. Vision has improved and the scotoma is disappearing. Neither case had sinus therapy. I recall a case I saw about three years ago in which a healthy young man of about 18 years of age came to see me giving a history of rapid loss of vision. After a few days his vision was reduced to hand movements in each eye and there was an edema and a swelling of both optic nerve heads. A competent rhinologist could not find any pathology in the sinuses and declined to operate. The patient was sent to another rhinologist who operated the sphenoid and ethmoids and found no pathology. The outcome in the case was that after about two weeks the patient developed a frank disseminated myelitis which after some six or eight months caused his death.

Last fall I saw in the clinic a child about 7 or 8 years of age who had rapidly within a short time lost his vision. This child had been advised to have his sinuses operated and was brought to the clinic for a confirmation of that opinion. The vision in each eye was hand movements and there was an advanced papilledema. The child was sent to the Neurological Institute for observation. Because of the rapidly advancing papilledema a decompression operation was done. Patient eventually lost light perception and after several months died. The autopsy showed that he had an internal hydrocephalus, a result of an ependymitis.

I cannot agree with the statement that there is no danger in operating the accessory sinuses. We all may recall the death a few years ago of one of our prominent confrères in ophthalmology subsequent to an operation upon his ethmoid sinuses, and I am quite sure we all have had cases that have had prolonged and annoying symptoms following operations upon their accessory sinuses.

THE MEDICINE OF THE FUTURE

By GEORGE W. CRILE, M.D., CLEVELAND, OHIO

Read at a public dinner meeting under the auspices of the Committee on Periodic Health Examinations of the Medical Society of the State of New York, the Medical Society of the County of Monroe, and the Rochester Chamber of Commerce, at Rochester, N. Y., on June 4, 1930.

MEDICINE and religion date back to the tribal stage ancestors. Their evolution has paralleled the general evolution of mankind. The fog of mysticism of the days of savagery is still present in lesser degree even among apparently cultured people, but is clearing away by degrees as science and education create and disseminate knowledge.

Among the tribes of African natives today—with their ignorance and fears and superstition—there is no organization to spread even such meager medical and biological facts as they recognize. An organization for the dissemination of knowledge must wait for science to supply the facts to be taught.

No one group or organization should attempt to monopolize intelligence, but schools, churches, health agencies, the Red Cross organization, etc., should work together in the dissemination of useful knowledge. Let us review some of the achievements of the accumulation and dissemination of knowledge—facts that we hold securely even now—and let us consider what may reasonably be expected in the future.

The mortality among mothers from puerperal fever has been reduced from 57 per cent fifty years ago to 0.08 per cent today, while infant mortality has been reduced more than 50 per cent in the past 27 years. Surgery and orthopedics have conquered most of the deformities of children. The oculist has corrected the defective eyesight of children. The infected tonsils, which once were the cause of so many damaged heart muscles, are now discovered early and removed. In many cases the onset of diseases of the heart and of the kidneys later in life may be anticipated by the prevention of contagious diseases in children.

Our knowledge of the value of the vitamins, of fresh air and sunshine, of proper plumbing and of sewerage systems arose primarily from a knowledge of disease. Antitoxins and vaccines are curing and preventing infectious diseases so that the great scourges of the Middle Ages cannot be repeated. Lockjaw is prevented by the injection of a serum. Yellow fever is under almost complete control—indeed that disease is in a fair way to being exterminated.

We have learned, too, that within the body certain organs form specific chemical compounds, and these compounds are thrown into the blood and influence distant organs. For example, there are four glands so small as almost to elude detection—the parathyroids, the removal of which is followed by violent convulsions and death; there are the two small adrenal glands, the removal of which causes progressive weakness and death; and there is the thyroid gland, the excessive activity of which speeds up the entire organism until a state of frenzied nervousness and intense oxidation is produced, with rapid loss in weight, a wearing-out of essential organs and ultimate death; while individuals with a deficient thyroid tend to become dull and sleepy and cold and flabby and fat and coarse. As a result of the study of these glands of internal secretion, remarkable advances have been made in the study of various diseases. The hormones of the thyroid gland and the adrenals can now be made in the laboratory or we may borrow each from the sheep or the pig. It is well within the range of possibility that with the general application of the principles worked out by many investigators, by Marine and his co-workers in particular, simple or endemic goiter with its sequellæ, cretinism, infantile and adult myxedema, idiocy, imbecility, mutism, nodular goiter, and a high percentage of malignant tumors of the thyroid, may be eliminated from among the scourges of mankind. The discovery of insulin by Banting and MacLeod provides a control for diabetes, a disease which in the past has claimed about 80,000 victims a year. And now Dr. Minot and his associates in Boston have found that the cause of pernicious anemia is a deficient amount of a certain substance in the liver. This substance has been identified and pernicious anemia is now curable.

The surgeon who performs hundreds and thousands of operations each year can now provide his patients with the solace of anesthesia, the protection of aseptic methods, the conservation of his bodily energies by the prevention of shock and the restoration of them by blood transfusion. Thus today, armed with the findings of scientific investigations, the surgeon successfully invades every part of the body, even the deep parts of the brain, and thousands upon thousands of men, women, and children are taken out of the path of danger and restored to health.

In another field, victories are being achieved. This age of continuous excitement, of fierce struggle, of heavy mental strain pays a heavy toll in mental breakdowns. In this field the newer psychology has strengthened the hand of the psychiatrist and many good results are being achieved.

As the result of the great diminution in the

hazards of childbirth, of our better knowledge of diet, of the control of infectious diseases, of the increased efficiency of surgery,—and to these must be added better housing, better food, better living conditions,—the span of life has increased as follows: In the 16th century the average length of human life was 18 to 20 years; in 1800, less than 25 years; in 1900, between 45 and 48 years; in 1924, 56 years. Not only is life longer but it is better —better physically, better mentally, and, I believe, better morally.

So much for the present. What of the future? What will be the trend of medicine in the last 70 years of this century which has already seen such remarkable progress?

I feel that I am justified in making the prophecy that before many decades the role of the physician will have changed to such an extent that his profession will seem an entirely new one as compared with the practice of medicine today. This change will be the result of many factors. Education in the public schools and universities and education of the public at large will have brought the public—at least the intelligent public—to a point where it will be as well informed along general medical lines as is the physician of today, and diet, hygiene and preventive measures in the treatment of the more common diseases will be matters of general knowledge. Consequently the chief duty of the physician will be to develop the race, to direct the development of youth and to guide the adult along sound biological lines so that he may safely engage in the maximum of work and of play. In other words, the physician will be called upon to study the whole problem of man in relation to his environment. As for disease, the physician will be more concerned with its prevention than with its treatment. In fact, treatment of disease some day will be a confession of failure.

The physical conditions under which medicine is practiced will also have undergone great changes. The division of the field of medicine into specialties will have been carried even farther than it is today, so that only a superman will be able to have a complete knowledge of the entire field of medicine.

As for the different divisions of medical science, the present outlook would seem to indicate that in the future their individual progress will vary greatly. Surgery will continue to make advances, but most of its obstacles have already been conquered, and its field will grow narrower as preventive medicine advances.

The field of the internist, on the other hand, will be widened by advances, particularly in his knowledge of the ductless glands and the mechanism of the mind—psychology, memory, reason. Every physician will be trained to understand the psychological problems of his patients as well as their physical ailments, for this will be made necessary by the increased nervous strain and resultant nervous exhaustion encountered even in the life of the average individual. It will be an interesting question in the study of evolution to observe how the nervous system will adjust itself to this increased strain. Nor will the adaptation of psychology be limited to medicine; practical use of it will be made in schools in an effort to adapt the pupils to their environment.

As for individual problems which we are now trying to solve, I feel that their solution will meet with varying degrees of success: Tuberculosis and diabetes will be conquered. The public will learn the importance of the early eradication of focal infections and the incidence of other infectious diseases will be reduced, and it will follow that to the extent that diseases of the heart and blood vessels, high blood pressure, and diseases of the kidneys are due to infections their incidence will be reduced. On the other hand to the extent that these diseases are caused by nervous and mental strain—by the kinetic drive of environmental conditions the incidence may even be increased.

The incidence of venereal disease will decline greatly. Because of the change in the attitude of the public toward it, venereal disease will be openly controlled. The hazard of childbirth will be even further reduced, but congenital deformities will occur with the same frequency. The span of efficient life will be lengthened still further. The nature of cancer will eventually be revealed, but it will still claim many victims.

It is in the field of nervous and mental diseases that we shall be "in red ink." The complicated mechanism of the web of life in which civilized man is enmeshed will lay a heavy toll on the brain and nervous system and on the ductless glands and in consequence on the heart and blood vessels and kidneys. Therefore as time goes on, there will appear an increasing number of wrecks. The reproduction of the unfit will be reduced and as a consequence there will emerge the beginnings of a superior race.

Within certain limits, therefore, the physician of the future will be able to control the growth of the body and the development of the mind. He will acquire such a knowledge of biochemical and biophysical processes that he will be able to guide his fellowmen as an engineer of living processes.

We may confidently expect that science will

reveal the nature of life—and with it the physical nature of mind and personality. These expectations are based on the achievements of chemistry and physics. The biochemist has been able to construct many of the compounds of which the body is made, and surely the end is not yet. The biophysicist has already identified the energy that organizes and drives living things; he has found that the physical laws of the living organism are identical with the laws of the non-living. It will be a long and difficult task for the chemist and the physicist and the workers in the medical sciences to reproduce the infinitely delicate balance between energy and form which endows the non-living with the attributes of beauty and movement, and growth, the reproduction, and memory and ends in unbalance with resultant death and disintegration. It is the task of the medical scientist to discover and control as far as he can the causes of man's infirmities and to prolong his useful life. But the layman as well as the physician has an important role to play in the achievement of such an ideal.

END RESULTS IN ECLAMPSIA*

By ALFRED C. BECK, M.D., BROOKLYN, N. Y.

From the Department of Gynecology and Obstetrics of the Long Island College Hospital.

THE material which furnishes the basis for this study consists of 97 consecutive cases of eclampsia treated in the past 16 years. During the first quarter of this period our chief consideration was the prompt removal of the products of conception. Having evacuated the uterus our attention was then directed towards stimulation of the emunctories and relief of the symptoms in the desperately sick mother. All cases were considered to be dangerously ill but we seldom swerved from the principle that the removal of the cause of the toxemia, the living products of conception, must be accomplished most promptly. Accordingly untimely and forcible measures frequently were employed. Among them were: manual dilatation of the cervix and forceps; multiple incisions of the cervix and forceps, vaginal hysterotomy, followed by version and extraction; high and mid forceps and even cesarean section.

Immediately after these anything but trivial operations, the unfortunate women who survived were subjected to eliminative measures that would have taxed the strength of a strong and healthy laborer. They included the use of hot wet packs, gastric lavage, croton oil and castor oil or magnesium sulphate by mouth, followed by frequent colonic irrigations, hyperdermoclysis and phlebotomy. Anaesthesia, morphine, chloral and veratrum viride often were added and the hypersensitive patient frequently was thrown into a convulsion by repeated catheterizations and blood pressure determinations.

To sum up the routine followed in this early period we might say that these desperately ill women were subjected to major operative procedures when they were poor risks for any operation and, surviving operation, recovery was further jeopardized by the use of eliminative measures little short of heroic.

Twenty-five per cent of these patients died. As I look back on this experience I wonder not that so many died from eclampsia but that so many survived the treatment.

These figures compared favorably with those of other clinics which like ourselves employed the accepted routine in eclampsia. However, when compared with the results published by Stroganoff and Tweedy, they were most disappointing. Although these men taught that the products of conception should not be disturbed, a principle then regarded as rank heresy, we felt that even this apparently unwise practice should be given a trial.

Throughout the next four years neither interruption of pregnancy nor the hastening of labor was attempted except for a definite indication other than eclampsia. Morphine in large doses was freely given and the milder eliminative measures were employed. While our results were much less favorable than those reported by the exponents of this routine, they were considerably better than any previously obtained by us.

About eight years ago the histories of all of our eclampsias were carefully studied with a view to further improving our routine. A separate chart was made for each case to show the relation between the various therapeutic measures and the onset of the convulsions. In over half of the cases in which a stomach tube was passed this procedure caused a convulsion. The insertion of a rectal tube occasionally, was immediately followed by a seizure. The same observation was made, only less frequently, in

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3 1930.

regard to catheterization, blood pressure determinations and hypodermic injections. These charts clearly showed that we often failed to recognize the fact that the woman suffering from eclampsia is hypersensitive to external stimuli and that convulsions may be provoked by very slight irritation.

Protection of the Patient: We now try to protect all eclamptics from unnecessary external stimuli. They are placed in a darkened room that is kept as quiet as possible. Gastric lavage no longer is employed. Colonic irrigations are given but once or twice in 24 hours. Whenever possible, hypodermics and other treatments are given during the coma that follows a convulsion. In doing a phlebotomy we withdraw the blood through a large paraffin-coated needle and thus avoid the irritation usually produced by cutting down a vein. Frequent blood pressure determinations and catheterizations are no longer done. In general we try to protect all eclampsias from avoidable irritation, just as is the custom in the treatment of tetanus, strychnine poisoning and hydrophobia.

Phlebotomy: The same study led us to feel that phlebotomy often was beneficial. This was particularly true in the cases where the blood was withdrawn soon after the onset of convulsions and was large in amount. As a result we included in our new routine early large phlebotomy. We aim to withdraw 1000 c.c. of blood through a paraffin-coated needle immediately after the first convulsion that occurs in the hospital. During the phlebotomy the blood pressure and pulse are constantly observed. If the blood pressure falls below 100 or the pulse rises rapidly the phlebotomy is discontinued, otherwise the full 1000 c.c. are withdrawn.

Morphine Routine: An outstanding fact also revealed by this survey of our records was the remarkable tolerance for morphine exhibited by the eclamptic patient. To obtain the desired effect it was necessary to repeat the drug in quarter-grain doses at hourly intervals. In some patients two to four grains were given within 24 hours. In one instance 4½ grains in 16 hours had no harmful effect on the mother or child. This tolerance for morphine led us to increase the initial dose to one-half grain and follow it with quarter-grain doses at intervals of one hour until the convulsions cease or respirations are below 12.

End Results: The routine just described has been in use for 8 years. During that time 48 women suffering from eclampsia have been admitted to The Long Island College Hospital. Three of these died, a mortality of 6.3% This figure compares most favorably with that obtained in the preceding 8 years when 49 women were treated for eclampsia and 13 or 26.5% died Details of the two series are shown in tables 1, 2 and 3.

Cesarean Section	2	0	0	1	50
Postpartum	21	2	9.5	—	—
Total	48	3	6 3	18	37.5

The low maternal mortality, we believe, was due in a large measure to early large phlebotomy. Our faith in this measure has been greatly strengthened by the fact that in 30 of the 40 cases in which phlebotomy was done not a single convulsion was observed after the blood letting.

The fetal deaths were high in both series. Usually the fetal heart disappeared within a few hours after admission. While the conservative routine in our hands has been most beneficial to the mothers it has given us very poor fetal end results.

THE HEALTH OFFICER'S DUTY IN TUBERCULOSIS CONTROL*

By ROBERT E. PLUNKETT, M.D., ALBANY, N. Y.

PREVENTION, as in all public health work, is the keynote of tuberculosis control. The successful application of the principles of such control depends upon two fundamental factors; first, a properly trained and qualified health officer; and second, the proper facilities such as dispensaries, sanatoria, and public health nursing service.

Inasmuch as the character of tuberculosis work in a given community is usually in direct proportion to the ability of the health officer, a few words concerning the qualifications of health officers are appropriate. We all admit that the degree of Doctor of Medicine alone does not make a health officer. Our attention has been directed many times to the fact that practicing physicians have not administered public health programs successfully. What, therefore, are the requisites for a health officer?

He should have academic and scientific training, which equips him to appreciate the manifold health problems of a given community. To determine the magnitude of the task of tuberculosis control, he must have mortality, morbidity, economic, industrial and social statistics covering his district. He should be qualified to evaluate these data with precision in order to map out intelligently the various and sundry methods of performing the necessary work. He should have an apperception of modern scientific methods in research and practice, so that his efforts will be guided wisely and in the most effective manner. He should have the ability to prepare and present tables, graphs, maps, and similar data in a manner which clearly sets forth their significant features and the things which should be done. These are very valuable in discussion, especially in securing financial support for a project.

There is no more amenable, yet at the same time insidious, enemy to public health than the tubercle bacillus. This organism is usually able, or is forced by what we term resistance, to abide within our bodies for years, without causing any appreciable disturbance to our bodily functions. Small and intermittent doses of tubercle bacilli may even afford a good future protection, but we know that massive doses usually lead to tuberculous disease, adding other foci of infection to those with which we must deal.

What can the health officer do to combat present foci of infection and prevent the occurrence of future ones? From the academic side of administration must come the statistical data which have been compiled. The reporting of every tuberculosis case is the very essence of the general application of a prophylactic program and not by any stretch of the imagination has it assumed, the proportions it deserves in this State. Of all the statistical data necessary for the proper evaluation of a tuberculosis problem none are more important than those pertaining to morbidity and mortality.

Every community should report three new cases per one death each year and the health officer should have a record of at least six existent cases per one death in a given year. Although the law does not require the recording of contacts, the health officer should maintain an active file of all sputum-positive contacts.

The home of every reported case should be visited, studied, and classified. When a case is reported the health officer should lend his efforts toward assisting the attending physician in the elements of prophylaxis. He should appreciate the value of sanatorium treatment, and advocate it from the standpoint of therapeutics, prophylaxis and education. He should assist in giving hygienic advice to reduce to a minimum the spread of infection. He should promote constantly repeated examinations of sputum from suspected cases, a procedure which is badly neglected at present.

He should also obtain the periodic examination of contacts, and offer diagnostic facilities to those who cannot afford a private physician. Through the agency of his public health nurses he should carry on a continuous campaign of education in the homes of patients, and lend his good offices in securing and maintaining proper standards of operation of the sanatoria to which he sends patients.

In addition, he should study each case, not as such, but as a home and a family, with its possible social and economic effect upon the community. He should sincerely appraise the economic handicaps of the families of patients. Greater use should be made of the law which makes provision for financial help to mothers while the father is under treatment in a sanatorium, or after his discharge until he is able to return to work. The health officer can, and should, assume responsibility in promoting such subsidies.

At times I have heard so much concerning standards of work and charts of classic organization that I wonder if we ever think of a case except as such. There is a type of qualification for a health officer or any public official, aside from scientific training, which cannot be measured by charts or statistics. This I shall term the emotional, or humane quality, of health administration. A health officer should apply the same compassionate consideration to a family in which there is a case of pulmonary tuberculosis, as a surgeon does in determining whether a

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930

patient should or should not have a serious operation.

Should a health officer become exercised when he has a case of smallpox in the community, and be relatively unconcerned about the ravages made by a sputum-positive case in a home where there are four or five child contacts? Is this reaction due to traditional fear of one disease and ignorance of the other, or is it due to discouragement with the prolonged and unspectacular vigilance necessary to prevent the latter disease? If the health officer feels his responsibility in this human problem, I am sure his reward will be golden and his success certain.

In closing let me summarize: The nucleus of factual data consists of reported cases, the cytoplasm consists of household contacts, the cell as a whole is the home, and the surrounding tissue is the community. Study and analyze the data; evaluate their significance, with true scientific spirit. Leave no stone unturned in securing sanatorium treatment, for a time at least, for every positive case. Encourage and advocate dietetic and hygienic measures for contacts to increase their resistance, and minimize chances of future breakdown. Advise periodic examination of these contacts.

From the emotional standpoint, study each cell with the microscope of fervor, its nucleus, its cytoplasm, and the surrounding tissue. Put yourself in the position of the patient, and of his family, and remember that the disease may result in more than the death of one patient. It will, by virtue of its etiology, become transmitted from one to others, unless we apply ourselves to education, both of the physicians and the public, in ways and means by which the disease can be controlled. Awaken your social consciousness. Appreciate the consequences to the patient, the family, and the community, unless your scientific and humane knowledge be applied in an understanding manner.

If public health is purchasable, tuberculosis prevention is a bargain, for, unlike many communicable diseases, we know its cause, its means of transmission, and methods of prevention. A case of tuberculosis, therefore, which is reported in the face of all our data and knowledge, is a confession of ignorance, or neglect, or both. In our efforts at success, however, may we never become so efficient in our administration that we become indifferent toward our patients, and forget that a case is a human being, a house is a home, and the hope of the community lies in healthy, happy families.

THE DIAGNOSIS OF INTRA-PERITONEAL HEMORRHAGE FOLLOWING TRAUMA*

By A. B. SULLIVAN, M.D., NEW YORK, N. Y.

IN surgical practice hemorrhage is met with in two phases—External or visible bleeding which, regardless of how profuse or from whence its source, can be promptly and adequately dealt with insuring its arrest. The other is internal or, I might say, invisible bleeding such as occurs into the large cavities of the body, particularly the abdomen. No one will deny the statement that the latter phase of hemorrhage constitutes a serious condition for the patient and confronts the surgeon very often in an uncertain way, causing him no little anxiety and a difficult problem in diagnosis. Hence I present the subject of intra-peritoneal hemorrhage, in so far as it relates to a patient whose peritoneal cavity has been the seat of a sudden inundation by blood as a sequence of trauma.

On the service of a large general hospital every year one sees a relatively large number of patients admitted in a state of shock, with a history of trauma, whose symptoms are referable to the abdomen. Excluding those cases of penetrating stab and gunshot wounds, what means have we in determining quickly and positively whether or not a patient, following a fall or a blow upon the abdomen, is suffering with a concealed hemorrhage into the peritoneum? If the lesion be that of free bleeding, it is most essential that it be recognized as quickly as possible and exploratory laparotomy performed at once, since intra-abdominal hemorrhage is usually profuse and, if temporized with, too often fatal. But on the other hand, in a patient whose apparent shock is not caused by or accompained with intra-peritoneal hemorrhage, error in judgment and exploratory operation in many cases is all that is required to insure a fatal outcome.

By analyzing the condition, I believe that certain points may be brought out which definitely indicate its presence and should thereby lead to early diagnosis and the prompt institution of the proper treatment.

Regardless of any primary violence sustained giving rise to intra-abdominal bleeding, the sudden flooding, with blood of the vast surface area of the peritoneum, which is so sensitive to invasion by foreign matter, constitutes trauma of no little moment. Here we have three factors—the initial trauma, the loss of blood from the general circulation and the

* Read before Bronx Surgical Society, May, 1930, and before the Yonkers Practitioners Club, October, 1930

peritoneal irritation by this blood, resulting in and quickly ensued by a fourth factor, namely, that of the so-called condition of shock. Hence in the rapid succession of these factors we are confronted with a multiplicity of conditions combining to create a constitutional emergency, graver and more serious than which I believe there is none.

In any discussion of hemorrhage, shock must be given a foremost place and dealt with, with frank consideration because of its constant presence in all cases of profuse or massive bleeding. Shock is a term used rather loosely to designate a bodily state seen in many conditions and in various degrees. Numerous theories there are, which by analysis of the known phenomena of this complex condition, endeavor to explain it, but lacking substantiation fall short of their purpose. In the literature it is universally conceded that there is no clear definition of the condition. Hence our knowledge of shock is limited to the facts learned by clinical observation, therefore our conception of it is best described by an account of these facts.

The following is an account given by Fischer[1]: The patient described by him was that of a young man who was forcibly struck in the abdomen by a heavy pole. The grave symptoms and alarming look which the patient presents made their appearance immediately after the accident. He continues: the man lies perfectly quiet and pays no attention to things about him. The pupils are dilated and react slowly to light. He stares purposely and straight before him. His skin and such parts of the mucous membranes as are visible are pale. Large drops of sweat hang on his forehead and his whole body feels cold to the hand. A thermometer indicates 1 deg. centigrade below normal by rectum. Sensibility is much blunted over the whole body and only when a very painful impression is made on him does he fretfully pull a wry face and make a languid defensive movement. The pulse is almost imperceptible and very rapid. The arteries are small and the tension low. The patient is conscious but replies slowly and only when importunely questioned. His respiration is characterized by long, deep sighing inspirations, alternating with very superficial ones which are scarcely visible or audible.

Cowell[2], who has had extensive opportunity to observe shock in wounded soldiers; has divided shock into two groups: Primary and Secondary.

Primary shock is seen, he claims, when the damage sustained by the body is so great that death must supervene unless surgical intervention is soon available. The blood pressure falls rapidly and all the symptoms of shock are observed as soon as the patient is seen. It is Cowell's judgment that such a state rarely occurs except when associated with hemorrhage. This I believe to be true and it is the factor, in which we are particularly interested, in intra-abdominal bleeding.

Secondary shock, Cowell says, is the type which follows several hours after injury and is partly attendant upon certain factors superimposed upon the initial trauma, such as exposure; anesthesia; surgical manipulation or continuous loss of blood. It may or may not have been preceded by a state of primary shock. Primary shock may be recovered from, at least partially, but, however, it is likely to develop into the secondary form. This period of recovery is called reaction.

In studying Cowell's analysis of shock and associating it with my own observation, I shall divide internal hemorrhage into four stages: First, there is the stage of hemorrhage. This is quickly followed by the second stage, that of primary shock. With the second stage there is without doubt a cessation or a marked diminution of the bleeding. At this point the patient reaches a crisis and, either death intervenes or the patient passes on into the stage of reaction, in which we have a resumption of the bleeding, leading into the fourth stage, secondary shock ending in ultimate and certain death. Thus it is clear that the sooner hemorrhage is recognized and arrested, the better are the patient's chances of recovery, primary shock, under the circumstances, being no contraindication to immediate operation.

Very often we are confronted with the problem of differentiating shock, which is the direct result of trauma without hemorrhage and shock, which is the result of trauma with concealed intra-abdominal hemorrhage. The symptoms of hemorrhage as enumerated in surgical texts differ none whatever from those enumerated in Fischer's description of a patient in profound shock. Thus it would seem to follow that the dictum uttered by the older generation of surgeons, that shock is hemorrhage and hemorrhage is shock, receives a striking confirmation.

It has appeared to me that the striking and essential difference between traumatic shock without loss of blood and shock due to hemorrhage is one of intensity. In this connection, I have observed and recognized a condition, simulating shock, which I believe is brought about by violent afferent nerve impulses causing a general vital depression, the direct sequence of trauma, without loss of blood. This state of depression I call collapse, preferring to associate the term shock with a most alarming condition directly related to the loss of blood. This depression, which I designate

Collapse, may be seen with many conditions, none of which, however, being accompanied with loss of blood. Perforation of hollow abdominal viscera with peritoneal invasion by foreign and contaminated material, sudden occurrence of pneumothorax; pulmonary embolus; fractures of the long bones; fractures of the vertebrae; acute pancreatitis; spinal anesthesia; are some of the conditions accompanied by collapse.

I do not contend, however, that there is always a distinguishable difference clinically between Shock and Collapse, but on the other hand, I readily agree that the general depression associated with the state of Collapse may and often does closely simulate Shock. But if one can make a differential diagnosis between Collapse and Shock, then it is possible to distinguish between trauma without hemorrhage and trauma with hemorrhage. This difference, I believe, is the difference between pallor and restlessness in Shock and hemorrhage and lividity of the skin and general apathy in the Collapsed state; these factors plus the other commonly observed symptoms and signs seen in both Shock and Collapse.

A patient might suffer visceral injury without hemorrhage and, even if we concede the perforation of a hollow organ with peritoneal contamination, still the individual is spared that which is denied the patient with hemorrhage; the loss of blood from the general circulation, the latter factor constituting an immediate and most serious complication superimposed upon an already existing serious lesion.

A factor which has stood out in my observation is in the elicitation of the physical signs. Tenderness and rigidity may be very slight even in the presence of considerable hemorrhage. This is due to the sluggish response of a shocked patient to painful stimuli; and since the degree of an abdominal emergency is often determined by the intensity of the tenderness and rigidity present, the absence of marked signs must not lead to temporizing, but rather on the contrary, should point very strongly to a suspicion of bleeding.

Pain in one or both shoulders and scapula regions is, in my opinion, a very significant symptom of blood in the peritoneal cavity. The phenomena is explained by the irritation of the diaphragm by blood clots in the perisplenic and subphrenic spaces. It is essential here to rule out injuries to the thorax and its contents. This is not difficult, as a rule, by simple physical examination. I was greatly impressed by the importance of this symptom very recently, when over a short period of time, I observed this complaint as a most outstanding feature in four cases of intra-abdominal bleeding. Two cases of ruptured spleen, one with spontaneous rupture operated on by me; the other case that of latent hemorrhage from the spleen following trauma, operated upon by Dr. Cunniffe Splenectomy was performed in both cases and both patients recovered uneventfully. The other two cases presenting this symptom were patients with ruptured tubal pregnancies; both being in the right fallopian tube. These two women complained of intense pain over the lower right side of the thorax, the pain radiating to the right shoulder and scapula regions.

The blood picture immediately following hemorrhage is essentially a prompt increase in the polymorphonuclear white cells, a leucocytosis of 20,000 being a common finding after sudden and profuse bleeding. The red cell count at first is almost entirely unchanged, showing very little, if any, variation from the normal. The hemoglobin likewise shows little or no change, the color index remaining "one." This is due to the fact that the loss of blood is primarily a loss of volume rather than a loss of blood elements, any given cubic millimeter of remaining blood showing a normal red cell and hemoglobin content. Later, however, when the body tissue fluids are called upon to replenish the lost volume, the dilution is then manifested by a decrease in both red cells and hemoglobin. In the process of regeneration the production of red cells exceeds the production of hemoglobin, and the bone marrow turns out red cells with a lower hemoglobin content than normal. In other words, the color index becomes less than one and the picture is that of a secondary anemia.

Other symptoms and signs of intra-abdominal hemorrhage which do not, however, warrant elaboration, are restlessness, air hunger, thirst and dullness in the flanks.

CONCLUSION

(1) Intra-peritoneal hemorrhage very often presents a difficult problem in diagnosis.

(2) Shock indicates hemorrhage. Shock is Collapse plus something else. That something is loss of blood.

(3) Experience and judgment are the best aids to diagnosis. With both, cases still escape early recognition.

(4) Delay in diagnosis means the delay of that which is the patient's only hope of recovery—Immediate operation.

ESSENTIALS IN FRACTURES*

By JOHN J. MOORHEAD, M.D., NEW YORK, N. Y.

IN this day when accidents are so frequent, it may be profitable to review our knowledge as to the essential treatment of some of the more important fractures. We recognize that there is a widespread interest in the management of the injured because hospitals everywhere are now acting as service stations for the treatment of the traumata.

In the not too distant past, any hospital beyond a railway or industrial zone was rarely called upon to treat severe injuries. But with automobile transport, with aviation, with miles of new territory opened up by modern highways, the situation has changed, and today we are confronted by what in effect is an epidemic in injuries. This demand is by no means limited to the larger cities, but on the contrary, any town or hamlet contiguous to a good road, may be called upon to render a very specialized type of service to a group of patients capable of commanding and demanding the best grade of attention. This same type of patient stricken with appendicitis could perhaps with safety be transported to the nearest large hospital, but if the surgical emergency is traumatic, the treatment must be given at the nearest available hospital, and to be effective it must be prompt and it should be skillful. The problem is thus one of imminent necessity, and the profession everywhere are becoming alert because the demands are insistent and the supply of material increasing. To meet this law of supply and demand it is pertinent to state in some detail methods of treatment that have been tried out often enough to fulfill requirements.

What is a fracture? To me it means essentially a lacerated wound of bone, and if we will thus regard fractures, much of the confusion in treatment will disappear. Further, let us regard these bone wounds as being in the same class as soft part wounds. We are all familiar with incised and with lacerated wounds of the soft parts. Accordingly let us classify fractures in the same way, and thus we divide broken bones into two general Types. Type I is that group in which the bone ends are not in contact, they overlap or are otherwise displaced. This is like the lacerated wound class. Type II is that group in which the bone ends are in contact, they are not overlapped and they are not displaced. This is like the incised wound class. Either Type I or Type II may be simple (closed) or compound (open) fracture. Now the essential thing in the treatment of every fracture is to restore alignment, to convert the Type I into the Type II class. In other words we convert a side-to-side anastomosis into an end-to-end anastomosis. And in order to do this we know that in the reduction, traction of some sort is necessary. There are only two kinds of traction, namely, manual and mechanical traction. Manual traction is manipulative, and here let me urge the value of anesthesia in the setting of any Type I fracture. Nitrous oxide, drop ether or Ethyl Chloride are the inhalants of choice.

In certain joint fractures, as of the wrist, local anesthesia has a distinct field. In lower extremity fractures, spinal anesthesia is of value. Intravenous anesthesia as yet is not sufficiently standardized to be recommended. Now, obviously, the treatment required for a Type I or overlapping fracture differs from the treatment required for a Type II or non-overlapping fracture. The treatment of one is as different from the treatment of the other as is the treatment of a catarrhal appendicitis by comparison with a ruptured gangrenous appendicitis.

Hence treatment is summated in the four R's in the fracture lexicon—and these four R's are (1) Recognition; (2) Reduction; (3) Retention; (4) Rehabilitation.

(1) *Recognition.* What are the means of diagnosis? At the outset let us remember some clinical precepts, some of the laws of averages, some of the lessons of experience. Let me narrate some of these:

(a) If the violence has been adequate, suspect and expect adequate effects. This applies especially to injury by direct violence.

(b) Every joint injury associated with deformity and disability is a fracture and not a dislocation in about 75% of the cases, the shoulder joint excepted.

(c) In any person aged 50 or over, diagnose fracture of the neck of the femur before consigning that hip or that patient into the contusion-sprain class.

(d) Every wound not made with surgical intent is already infected and should be so regarded and treated. Hence all compound fractures are in that group.

(e) Be especially on guard in respect to injuries of the back and region of the pelvis, for fracture of the spine and fracture of the pelvis are exceedingly common in the absence of classical signs.

(f) Beware also of head injuries, for skull fracture is vastly more frequent than we realize.

(g) Finally, if in doubt, suspect fracture, treat for fracture, prognosticate fracture, until clinically or by *x*-ray all doubt is removed.

(2) *Reduction.* This is the keynote of fracture treatment, this the essential step in management. As has been indicated, there are two Types; namely, Type I with fragments displaced, and Type II with fragments not displaced. Now in this latter, the non-displaced type, we need no

* Read October 7, 1930, before First District Branch of the Medical Society of the State of New York.

reduction at all if the general alignment is maintained. Hence we let these alone and merely apply a suitable splint. But what is the index of general alignment? In the upper extremity, the anterior line runs from the acromion to the midspace of the elbow, thence to the mid space of the wrist, thence to the middle knuckle The *lateral* line starts at the acromion, thence to the external condyle of the humerus, thence to the radial styloid.

In both instances the position of the extremity is full supination, or palm up. In the lower extremity, the *anterior* line begins at the spine of the ilium, thence to the middle of the patella, thence to the mid-ankle and thence to the interspace between the first and second toes. The lateral line begins at the spine of the ilium, thence to the external condyle, thence to the external malleolus. In both instances, the limb is flat and the ankle at a right angle. However in the Type I or displaced group, the process of converting an overlapped into a non-overlapped fracture is the first act of treatment. Hence traction and manipulation are employed. If manual traction methods are attempted we should have full relaxation, and hence anesthesia is necessary, as already indicated. If however manual methods are *ineffective* or are *likely to prove unavailing*, we resort to mechanical traction methods. The simplest form of mechanical traction is by the use of adhesive plaster so arranged that the pull is *in the axis of the upper fragment*. We so arrange our apparatus that counter-traction is obtained, and we apply the maximum of weight at the outset. Right here it is pertinent to say that some sort of *provisional traction* should be applied to every case just as soon as the diagnosis is made. A towel or sheet around the ankle or wrist is often enough, and if this simple expedient is used, we will have the satisfaction often of finding our fracture reduced after a few hours This applies especially to cases seen when for a variety of reasons the patient is not ready or we are not ready for the application of definitive splintage. Do not wait for the *x*-ray confirmation, nor for more perfect paraphernalia If we reduce now, we avoid complications; if we reduce later, we invite complications. Adhesive traction reduction is most applicable in the humerus, and to a lesser extent in the upper leg. In the forearm, femur and lower leg it has so often proved unsatisfactory that other methods are necessary. For overlapping fractures of the forearm that do not yield to manual traction, my practice is to perform open reduction, and then self-notch the fragments, suturing by chromic gut if necessary.

If the fragments are not serrated, then they are deliberately notched by a rongeur. If there is a long prong on one fragment, this is reshaped so that it will fit into the medulla of the other fragment. The first plan we call "bone notching"; the second plan is "bone steepling." This same practice is used in certain other long bones also, and since we have employed it, bone plating has not been necessary. Here let it be said that the use of non-absorbable material in bone surgery is now almost as much out of fashion as is the use of non-absorbable buried suture material in soft part surgery. In the long ago, silver wire was used by some gynecologists and by some herniotomists; but the procedure is *now* in the limbo of wooden-handled instruments.

Hence metallic plates, screws, nails, clamps or wire are very rarely necessary. Personally I have *not plated a fracture in more than a decade*, and in that interval have used wire sutures only three times, and in each case the humerus was involved.

In the femur shaft group we believe skeletal traction to be the most efficient method when:

(a) The fracture has remained unreduced 24 hours or more, or has resisted the usual methods of reduction
(b) The fracture is in a muscular patient.
(c) The fracture is in the supra-condylar region.

Under these circumstances our experience is that a choice has to be made as between skeletal traction and open operation, and of these we regard the former as by far the safer.

We prefer the nail to the tongs or the stirrup as a *means of traction, and always employ the* one-piece rather than the two-piece nail.

We attach a very heavy weight from the outset in our femur group, often starting with a *weight of 40 pounds. After 48 hours, this* can gradually be reduced and at the expiration of 7-10 days, the nail usually can be withdrawn and plaster of Paris substituted. In order that the *whole procedure may be a one-stage affair*, we introduce the nail and leave free a space of about six inches above and below, covering the rest of the thigh and leg in plaster just as in any other spica When our reduction is found satisfactory, we fill in this window with plaster, let it harden, *x*-ray again, and if all is well, withdraw the nail through the plaster. All this secondary part can be done with the patient in bed and thus there will be no chance of upsetting the correction.

After union is solid (usually in 6-8 weeks) we apply walking callipers and make the patient ambulatory.

Skeletal traction in this group has rendered a great service and has simplified the management of what has hitherto been regarded as one of the serious problems in fracture surgery. To me the most difficult and potentially crippling fracture of all relates to the supracondylar group, and it is in this zone that skeletal traction has rendered signal service

In passing, let me extol the merits of preliminary aspiration of the knee in fracture of the shaft of the femur, for we know the frequency of the associated hemorrhagic synovitis and the direful effects of a stiff knee.

Skeletal traction is also of great value in that

large group of fractures of the lower third of the leg in which we have hitherto resorted to open operation. This area is notorious for the frequency of compounding and for the frequency of non-union. In my experience there is more non-union in this zone than in all other zones combined. The skeletal traction for this area is introduced through the os calcis in preference to over this bone or into the malleoli. Here again the principle is used of introducing the nail and applying the plaster at the same session, a window around the nail being left open to be subsequently filled when reduction is attained.

In certain fractures of the lower humerus, a nail or wire passed across the olecranon fossa makes an excellent traction device, using due care to avoid the two main nerves at the joint margins.

All in all then, we are partisan to skeletal traction believing that we are thereby relieved of the trials and dangers of open operation. Another point: as a preliminary to open operation, we often use skeletal traction in ancient cases where we know muscular contraction will be hard to overcome. Likewise in that old group of union with deformity, we introduce the nail below the fracture site and then do an osteotomy through the fracture line in preference to a step-down or other type of bone plastic.

What cases do best when operated upon? In our experience, fracture of the patella and olecranon are subjected to suture in the vast majority of cases. Next, as stated, we rely mainly on open operation in many overlapping fractures of the forearm.

Recently we have been using a motor driven device for reducing certain fractures not amenable to ordinary or skeletal traction, nor yet regarded as being wholly suitable for open operation. This contrivance we call the Repositor and in essence it motorizes the fracture table. We attach straps to the limb and fasten these to the Repositor and so arrange the traction that we can exert a pull from zero to 100 pounds. It is on the pull and let-go principle, a systole and diastole so to speak, in that the elasticity of the muscles will not be compromised.

It is on the principle of labor pains, and we can regulate the extent of the pull in pounds, the speed of the pull in five stages, and the length of the pull from zero to 7 inches.

We are quite certain that in some joint fractures and in some shaft fractures there is a field for this device. Of course, for stiff joints it makes a most efficient arthromotor, and in fractures of the spine it has rendered good service.

(3) *Retention or Splintage.* We believe in making the splint fit the patient rather than trying to make the patient fit the splint.

Hence moulded plaster of Paris is our favorite form of splintage. We rarely use a circular plaster of Paris casing in fresh fractures.

Our plan is to remove half the splintage when union is *firm,* usually between the second and third week. The rest of the splint is removed when union is *solid.* We like walking splints in certain leg fractures, and these are made by a U-shape of strap iron fastened to the plaster with one inch of it protruding beyond the sole so that the patient walks on this as if on stilts. Walking callipers are great aids in thigh and leg fractures because the crutch-bearing period is thereby much shortened.

(4) *Reconstruction or Functioning.* When can the part be used? The answer is when there is no reaction after certain test motions. We pound the fracture site, we push on the hand or nearest joint, we press against the foot, and then if there is no undue reaction in terms of redness or pain or swelling, then we proceed to allow moderate usage.

We try to gauge this ready-for-use stage not by the calendar but by the condition of repair, realizing that in some patients callus is abundant and in others sadly lacking or wholly deficient.

Skull fractures are not operated upon except for definite evidences of pressure and thus only two main groups are regarded as suitable for trephining; namely, the depressed group and the meningeal hemorrhage group. In the others, we relieve pressure by spinal tap, by glucose intravenously, by rectal drip.

Spine fractures are reduced by traction, by posture, by manipulation, by the Repositor. We believe that any case not relieved of intraspinal pressure by reduction can rarely be benefited by laminectomy.

Compound fractures are rarely subjected to primary suture, but on the contrary are carefully débrided, the stitches are placed but not tied until the 2nd or 3rd day. This is the War principle of primo-secondary or delayed suture and it is very earnestly recommended as a safety measure.

Here then are some of the essentials in fractures and some details of our own practice as to management.

Conclusions

(1) Reduction is the key to success.

(2) Early reduction means easy reduction, and provisional reduction should have wide application because fracture treatment is essentially of the emergency type and every hospital should be so staffed that traumatic cases will obtain immediate and not deferred treatment.

(3) Skeletal traction is of supreme value and often supersedes open operation.

(4) Splintage should be safe and it should be simple.

(5) Early usage is an element of after care that often makes physiotherapy unnecessary.

(6) Compound fractures should be treated by delayed suture rather than by primary suture.

UNDULANT FEVER*

By BYRON E. CHAPMAN, M.D., BROADALBIN, N. Y.

FROM the time Keefer first reported his case of infection with Brucella abortus in America, much interest and much research have been done with the disease, which here in America is branded as undulant fever. It bears a striking similarity to Malta fever and by many authorities is supposed to be the same disease. Whether Malta fever which was first observed in the Islands of Malta and has been proved to be produced in individuals who drink the milk of goats, which have been infected by Brucella abortus, interests us not so much today as the fact that we have among us the disease of undulant fever, which is contracted by drinking raw milk of cattle infected with Brucella abortus, or by contact with infected cattle and swine, or among laboratory workers who handle cultures and fresh pathological specimens from infected animals. The disease becomes all the more interesting because we have a definite means of laboratory diagnosis early in the disease and throughout the acute disease. It is possible by growing a culture in a carbon dioxide atmosphere to get a positive blood culture. The other means of definite laboratory diagnosis, and this has stood the test, is the blood agglutination test. Clinically the disease is variable, but the general symptoms are malaise, profuse sweating, chilliness, headache, and at times severe joint pains, and obscure gastro-intestinal symptoms. The disease will also produce abortion in the human as it does in the animal kingdom. The fever is intermittent and lasts from two to six weeks and usually the temperature is from 99-101 in the morning and from 101-105 in the afternoon. The pulse is noticeably slow. It ranges from 60-74 when the temperature is running from 100-105. The pulse and temperature curves very closely resemble a moderately severe type of typhoid fever. In other words, when a patient with a temperature and a pulse closely resembling typhoid and a lack of gastro-intestinal symptoms is seen and there is no other definite cause for the rise in temperature, one should do a blood culture and have a blood agglutiniation test done for Brucella abortus infection.

As physicians interested in public health, it seems appropriate to give a brief description of the disease in the cow which in the great majority of our cases is and will be our source of infection. The infected pregnant cow will lose her calf as a rule three to eight months after conception. She may or may not expel the placenta normally. Retained placenta in the cow with full term calving is always suspicious of a Brucella abortus infection. Cattle which are infected with Brucella abortus very commonly have mastitis and this is the source of our infection in our milk supply. Carpenter and others have shown that a high percentage of cows in herds infected with the Brucella abortus eliminate Brucella abortus organisms in the milk for a long time. Animals may continue to bear calves but persist in giving off abortus organisms. Veternarians claim the positive cows may give off the organism in the vaginal discharges from three to five weeks after calving normally or aborting. Since the cow contracts the disease through the digestive tract by drinking water or eating its rations which have been infected with these organisms, you can see how difficult it is for a herdsman to keep contaminating material from dairy utensils and his feet. Hence the rapid spread of the disease in cattle.

A brief description of nine of my own cases with some observations by other individuals will, I hope, give a picture of this disease:—

The blood agglutination titre in these cases was 1 to 80 and higher.

Case No. 1—Mr. W. G. Age 71 years, seen in 1926.

I was called to see this patient who complained of chilliness, weakness and generalized pains. His temperature was 101, pulse 68. He had marked tenderness in both wrists and knee joints with no redness or swelling present. The abdomen was moderately tympanitic and distended. He had no diarrhea, the examination was otherwise practically negative. Blood cultures and Widals taken several times over a period of three weeks were negative as were also two stool examinations for typhoid infection. The blood was negative for malaria. The white and red blood counts showed nothing particularly abnormal. This patient ran a temperature over a period of five weeks and then gradually recovered. No diagnosis was made at this time.

Case No. 2—Mrs. W. G. Age 72 years. (Wife of Case No. 1.)

Seven months after the first case I was called to attend this patient who complained of practically the same symptoms as her husband. The course of the disease was limited to three weeks. Since the occurrence of the first case, I had, as a breeder of cattle, become interested in abortus infection in cattle and on studying the literature had found that the disease occurs in man. Being on the alert for this disease, I immediately suspected it in this individual. Both these patients told me that for several years their evening meal had been bread and milk. Upon questioning the husband concerning his herd of cattle, I learned that during the two years previous they had had 7 cows give birth to premature calves. The blood samples were collected from the now ill

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1920.

individual and the husband who had been ill 7 months previous and were sent to the laboratory and tested. An agglutination test was done for Brucella abortus infection and a Widal for typhoid. The Widals were both negative and the blood was positive for Brucella abortus infection in both cases.

Case No. 3—D. P. School boy, age 11 years.

He complained when I first visited him of chilliness, weakness and pains in his ankles, knees, elbows and wrists. His temperature was 101.6. His pulse was 74. He gave a history of constipation. The next morning when I visited him his symptoms were practically the same, and again in the late afternoon when I saw him he was drenching wet with perspiration. Blood counts were taken which were practically normal, except for a slight secondary anemia. The Widal was negative as was also the blood culture. A few days later we received a positive agglutination test for Brucella abortus. The acute course of this boy's disease was practically three weeks. The joint pains were present for a period of eight days. He made an uneventful recovery and has never had a relapse. His father stated that during the last year he had slaughtered four cows which had given birth to premature calves. This is about as young as this disease is seen and fortunately does not often attack children in the first decade of life when milk plays a big part in their diet.

Case No. 4—Mrs. J. K. Age 34 years.

This patient three years previously had normally given birth to a full-term, healthy baby. I did not see her until I was called to attend her on the day that she aborted. She gave a history of being five months' pregnant and had felt perfectly well up until four weeks previous. During these four weeks she stated she had tired out easily, felt very weak, had run a slight temperature in the evening and instead of progressively taking on weight, she had lost several pounds. Later this day she expelled in toto a macerated placenta and fetus. Her temperature was 100.8, pulse 70. The Wasserman was negative and the blood agglutination was positive for Brucella abortus. This patient was the wife of an owner of a farm and they received their milk supply from this farm. Later a blood test of the cattle on this farm showed that 16 out of 39 were positive for Brucella abortus. Incidentally, it is interesting to know that I delivered this same woman 20 months later of a perfectly normal baby and she experienced no difficulty during the time she was pregnant. This has been the experience of other men. It has also been found with the experience of others that women with no known reason who have repeatedly aborted have given a positive blood agglutination test for Brucella abortus.

Case No. 5—Mrs. E. P. Age 36 years.

Six months after the previous case aborted, I was called to attend the wife of the tenant farmer of the farm mentioned in the previous case. She gave a history of being three months pregnant and having felt perfectly well up to this day when she had a bloody show from the vagina and was having intermittent uterine pains. She aborted several hours later a normal-looking fetus and placenta. She gave no history which might have been suspicious of abortus infection in any way or might have been responsible for an abortion. On account of the experience with the previous case blood was collected. The blood culture was negative, the Wasserman was negative but she gave a positive agglutination test for Brucella abortus. This case varies from the preceding one in that an apparently normal pregnant female aborted, who on examination of her blood showed that she was positive for the Brucella abortus infection.

Case No. 6—W. D. Age 74 years.

This patient complained of generalized pain, weakness and pain in the epigastrium. His temperature was 102.4 on the first visit and his pulse was 68. On physical examination nothing definite was found which might have accounted for his symptoms except slight tenderness on pressure in the epigastric region and over the gall bladder area. There was slight tenderness over the upper left abdominal quadrant but not so tender as over the gall bladder region. This case was treated as an acute cholecystitis. After remaining in bed for a period of two weeks his temperature subsided and his abdominal symptoms disappeared. He remained in bed 10 days more and we were about to let him up when he had a rise in temperature with no abdominal symptoms. This temperature persisted for a week when we collected blood samples for a culture, Widal and agglutination test. The Widal and blood culture were negative. The agglutination test for Brucella abortus was positive. This time the temperature ran over a period of four weeks and finally subsided. He has since totally recovered, never having had another relapse. This patient drank milk from a herd which was definitely infected with Brucella abortus.

Case No. 7—H. D. Age 45 years.

This patient complained of headache, pains in several joints, chilliness and fever. He was seen during a mild epidemic of influenza and was first considered as such a case. After his temperature had run over a period of ten days and the marked disparity between the temperature and pulse was noted, his blood was collected for blood culture, Widal and agglutination test. His test was positive for Brucella abortus infection. He ran a temperature for five weeks when it finally subsided and he made an uneventful recovery with no relapse. This patient owned a herd of cattle and stated that two cows which he had bought several months before had aborted their calves. It might be interesting also to men-

tion here that this same man kept sheep, a number of which in the following early spring also lost their lambs prematurely.

Case No. 8—Mr. L. C. Instructor in a New York State Agricultural School.

This patient first complained of weakness, headache and generalized grippy pains. Upon examination he was found to have a temperature of 104 and a pulse of 70. This temperature ran over a period of five days with morning remissions before blood samples were collected. At the time of collecting these samples, he stated that the Agricultural School, with which he was associated had destroyed their whole herd of Holstein cattle because it was disastrously infected with Brucella abortus. He had drunk milk in the school which had come from this herd. The Widal and blood culture were negative but was positive in high dilutions for Brucella abortus infection.

Case No. 9—W. S. Age 29 years

This patient complained of weakness, generalized grippy pains and profuse sweating at bed time. He stated that he had previously been ill two different times the same as he was this day and had each time been confined to his home about one month. The interval between these attacks had been approximately six weeks. He stated that he had had several different diagnoses made on himself. At the time that I saw him his temperature was 102 and his pulse 70. He showed a marked secondary anemia, otherwise his physical examination was negative. This same day a blood sample was collected and the following day a report of a positive agglutination for Brucella abortus was given by the laboratory. The Widal, Wasserman, and blood culture reports which were later received were negative. This attack lasted for a period of four weeks. Six weeks later I saw him with a similar attack which lasted two weeks. It has now been four months and he has not had another wave.

You may note that blood cultures were negative in all of my cases but this was due to lack of a CO_2 atmosphere in incubating. Laboratory men inform me cultures should be incubated for at least three weeks before being discarded as negative growths.

This disease presents a milk health problem which I believe can be handled in one of two ways, one is to allow the sale of raw milk regardless of tuberculosis accreditation or other certification only from herds which are entirely abortion free (and the agglutination test applies to animals the same as the human) and which continue to be abortion free as shown by repeated tests of all cattle in the herd at 3-6 months intervals. I appreciate that there are now few herds which can at present stand this test and the blow it might be to many herds, particularly certified herds which have been formed at great expense. The other means is by effective pasteurization which has many times proven its worth, not only in combating this particular infection but in many other milk-born diseases. In summarizing, we may say that undulent fever is caused by Brucella abortus which is present in milk of cattle infected with Brucella abortus, second that the disease can be definitely diagnosed by blood culture and by the blood agglutination test, third that the disease apparently does not attack individuals in the first decade of life but appears at all others, fourth that the disease is an economic loss to the dairy industry and a tragedy to the individual who has repeated relapses and to the female who is unable to bear children, fifth the disease can be controlled by proper supervision of herds tested abortion-free and kept so, or more particularly by the pasteurization of all our milk supply and milk products.

MUCOCELE OF THE APPENDIX*

By CHARLES D. SQUIRES, M.D., BINGHAMTON, N. Y.

THE objects of this paper are to review the literature of a comparatively rare condition involving a rather obscure pathological process and to present a recent case.

Verchow first described this condition in 1863, since which time 168 cases have been reported. Elbe compiled the cases that were published up to 1909 and found 150. Dodge in 1916 reported 142 cases in the literature, and Davidson in 1922 was able to add 18 more, making a total of 160 cases reported up to and including 1922.

Of the etiological factors of this condition, little is known. However Elbe believes the following underlying conditions are essential:

(1) A slowly stenosing process at one or more points in the lumen, as a rapid stenosis would produce gangrene.
(2) A sterile lumen must be present either distal to or between the point of stenosis.
(3) There must be an actively secreting mucosa or at least one in which the secretion is more rapid than the absorption. Also some change in the mucosa whereby mucin is transformed into pseudomucin.

Certain types of mucocele are considered potentially malignant, because of the fact that rupture may result in a reactionary peritonitis of the progressive type known as pseudo-myxomata peritonei. Mucocele of the appendix is the only known cause of the phenomena to occur in the male. It is one of the two causes in the female. The other is ruptured ovarian cyst.

* Read before the Binghamton Academy of Medicine on May 20, 1930.

The simple, uncomplicated, unruptured mucocele is a benign tumor in structure. That pseudomucin from a ruptured mucocele or from contamination during operative procedure, produces a generalized carcinomatous condition of the peritonium is a fact. The pathological process of this phenomenon remains an unsolved problem.

The symptoms of this condition are many and varied. They may conform to the text-book type of appendicitis, others present symptoms not unlike those attributed to volvulus intussusception or obstruction of the bowel. Still others present no symptoms whatsoever and are first made known on the post-mortem table or during laparotomy for some abdominal condition.

The pathology of the condition seems the most interesting. An appendix may contain two or more cysts, connected with each other in cord-like fashion, with the remnants of a stenosed appendix, the whole structure resembling a section of a string of beads. Others present a solitary tumor at the tip, supported by a pedicle, there again the result of a stenosed appendix. If the occlusion is at the base, the whole appendix becomes transformed, assuming the shape of a sausage, the largest ones taking the shape and size of a football. The external appearance of the cysts varies with the size, the amount of fluid they contain and the tension which the walls are under. The smaller the tumor the thicker the walls. As the tumor increases in size, however, the walls become thin, translucent, present a dull glistening surface, and due to the pressure are almost avascular in appearance. On palpation they feel like an inflated toy balloon; when pressure is exerted on one part of the tumor there is an even compensatory bulging of the remaining part, only to return to its normal size when pressure is released.

Histologically the appendix shows changes of a chronic inflammation in those areas not occupied by the cyst. At the site of the cyst, the condition varies with the size. The thick wall of the smaller tumor conforms more to the normal gut wall; however as they enlarge, the mucosa becomes thinned out, the muscle coat becomes obliterated, and a replacement of fibrous tissue takes place. The contents of these cysts present rather a uniform appearance, consisting of partially congealed jelly, sticky and tenacious and giving a positive test for pseudomucin.

The cases in which the contents are serous and not mucoid are not true mucoceles, but are of the more rare type, that is hydrops of the appendix.

Case Report

Female; age, 56.

Past History: No unusual sickness, one child living and well. No miscarriages, no digestive disturbances, bowels regular, appetite good.

Present Complaint: On Nov. 10, 1929, taken with abdominal cramps and diarrhea. At this time there was no elevation in temperature, or acceleration in pulse rate. These symptoms subsided in 12 to 15 hours and the patient was as well as usual. On Nov. 15, the symptoms occurred again with increased severity, the stool was light brown and watery in appearance. At no time was there any macroscopic blood. At this time patient took a mild laxative, accompanied by an enema which gave her complete relief in a day's time. On the evening of Nov. 20th I was called to see her in her home. She was complaining of severe abdominal pain, periodic in character, accompanied with the usual loose stool. Pulse 84, temperature 98.4. Abdomen slightly tympanitic, no localized, but slight general tenderness, contour normal, no rigidity, nausea or vomiting.

The patient was seen early on the morning of the 21st, she had vomited once during the night, still having some pain and slightly increased tenderness in right lower quadrant. Hospitalization was advised.

Physical Examination: Well nourished, well developed female. Head, neck, and chest normal. Abdomen tympanitic, no rigidity, increased tenderness over appendicial area. No palpable tumor. Some varicosity of lower limbs. Vaginal examination was of no diagnostic value. On admission pulse was 84. Temperature 98.2. Blood count 17,500 white, 92% polys., 8% lymphocytes. Urine negative.

Operation advised—abdomen opened through a right rectus incision. On exploration a mass was felt in region of the hepatic flexure, freely movable and with little care delivered into operative field. This mass consisted of an enlarged appendix invaginated into the cecum. The only visible part of the appendix was its tip. The intussusception was of a sufficient degree to obstruct the ileo-cecal valve. In the two previous attacks the active peristalsis of the gut was sufficient to release the obstruction.

By careful manipulation the appendix was delivered from the cecum, and the appendix removed by partial resection of the cecum. The appendix was about 4 in. long and 2 in. in diameter at its base. The mucosa of the appendix protruded well into the cecum. The contents of the appendix were mucoid in appearance, gelatinous and sticky. In this instance the occlusion occurred at the base of the appendix and was complete.

In conclusion:

(1) Mucoceles of the vermiform appendix are comparatively rare.
(2) They are true retention cysts probably caused by chronic inflammatory changes.
(3) They are potentially malignant. The metastasis, however, does not occur until after rupture of the cyst.

Office at 15 Park Place, New York. Telephone BArclay 7-5550

Counsel—LORENZ J. BROSNAN, ESQ. *Attorney*—THOMAS H. CLEARWATER, ESQ

Executive Officer—JOSEPH S. LAWRENCE, M.D., 100 State St., Albany. Telephone Main 4-4214

For list of officers of County Medical Societies, see this issue, advertising page xxxii.

Next Annual Meeting, Hotel Syracuse, Syracuse, N. Y., June 1, 2, 3, 1931.

DR. E. ELIOT HARRIS

The progress of the Medical Society of the State of New York is a reflection of the life work of Dr. E. Eliot Harris, who died in his home at 33 West 93rd Street, New York, on the morning of last Wednesday, February twenty-fifth. His fifty years of medical life were passed in the service of the profession as well as of the public. Graduating from the New York University Medical School in 1880, he at once began that leadership in organized medicine which he retained for half a century. His name was prominent in every annual list of committeemen and officers of the State Society. As speaker of the House of Delegates, his was a delightful exhibition of the science and art of parliamentary practice which was as pleasing as it was effective. Every member of the State Society accorded him that love and respect which he showed to them.

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—NO. 17

It seems like a journalistic achievement to give to the physicians of the state in their own journal as prompt news as the press of the state gave of the report of the investigations of the Special Health Commission appointed by the Governor last May.

The problem of publicity of medical news so as to arouse the interest of the profession is considerable. When bulletins of the committees on Economics, Legislation, and Public Relations are sent out to key-men in the counties, there is a definite response although these same reports have been published in the Journal. Organized medicine should carefully think out the value of close contact reporting of activities as a basic essential for better medical organization for the purpose of advancing the solution of the problems confronting the medical profession.

The rising tide of interest all over the state this year indicates that there is a beginning understanding that the day of isolation in medicine is over.

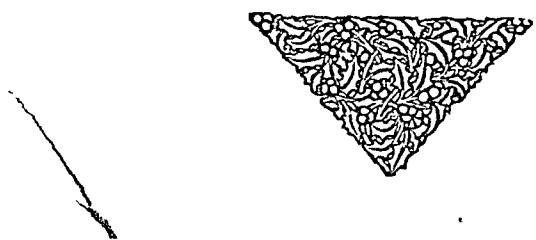
The individual relation of doctor and patient only, no longer suffices. A doctor has in addition a relationship to public affairs and to the problems of the distribution of health and sickness service. These must be left for real solution to the medical profession, itself. If done by laymen without the leadership of medicine, it will tend to make of the practice of medicine a business instead of a profession.

The profession in this state is undertaking to meet public need in health service. In many counties the medical society is solving important problems. It often happens that this is not known beyond the county. To spread information to other counties of whatever is being done well in any county would be of very great value. The increasing contacts, year by year, of the officers of the State Society with the County Society meetings are a great factor in the steadily increasing medical interest in the public service obligation of medicine.

I have heard many County Societies discuss the problems of medicine this year in a different way from even last year. There is today more constructive thinking on the problems of medicine and its human relationships than ever before. There is an increasing understanding of the essential re'ationship between the doctor and the public. This is a most favorable attitude. It indicates that careful consideration is being given by the profession of medicine to public medical needs.

Last week I heard a discussion in the Ulster County Medical Society of how the medical profession might be able to establish a diagnostic cancer clinic and provide for the employment of an expert pathologist.

In Livingston County the medical society has established a sufficient standard fee for school hygiene work—a fee that will permit the doctor to give time enough to make a good examination. Boards of Education are cooperating in this effort to do better work. It was originated, however, by the County Medical Society. It has behind it common sense and the public now views it in the same way.



Just as much as self government depends upon majority rule, medical organization should have unanimous support of its own members when it has reached conclusions by conference of its component parts.

The profession of medicine is properly, relatively independent and individualistic in scientific medicine and in the individual application of it in practice. In all other respects it should act by unanimous opinion after it has taken pains to carefully form that opinion. It is necessary to have medical organization for long understood reasons. In recent times it has become necessary in order to have a means of self-expression. Medicine is the only competent body to solve the technical problems of health and sickness service, rising from the rapid social evolution going on throughout the world.

The moment that responsibility for meeting social medical problems is shifted entirely from the medical profession, bureaucracy begins with its lack of understanding and its lack of human sympathy. It is, of course, not expected that the profession of medicine can assume the function of government in supplying administrative equipment for the distribution of health service or material provision for adequate modern medical care; but the technical direction of this service and the distribution of it to individuals can only be done by the profession of medicine.

While civic health effort may create sentiment that results in the enactment of laws to improve health and sickness service, such as, the Public Welfare Law of 1930 in New York State, its satisfactory operation is due to the interest and cooperation of organized medicine. Every county of New York State in which this beneficent law is now functioning bears out this observation.

WILLIAM H. ROSS

A SOUND PROGRAM OF PARENT-TEACHER ASSOCIATIONS

Among the social agencies today endeavoring to do their part in the betterment of child health, none have greater potential value than Parent-Teacher Associations. New York State is well organized. There are more than eight hundred associations. They have a sound program. They understand that the entire responsibility for the child's physical preparedness for school rests with the parent, and that parents can make no greater contribution to the future of their children than to have existing physical defects corrected in advance of entering school. The Parent-Teacher recognition that the family physician is essential for the physical examination, because of his knowledge of other pertinent facts bearing on the health and environment of the child, is sound

The follow-up after a few months to see if existing defects have been corrected is the third essential. All school examinations are futile if they do not result in correction of defects found

Organized medicine should cooperate with the effort of the Parent-Teacher Associations. Their organization is a valuable addition to public health education. Their program is sound. Their recognition of the vitally important relationship of the family physician to the whole program of preschool physical examination and correction of defects found is a real contribution to the advancement of preventive medicine.

The Parent-Teacher Association is essentially a social organization for education and administration. The medical profession is willing to advise the program and to be responsible for the technical work, and in the same way that private practice is carried on This plan maintains the friendly and sympathetic interest of doctor and patient which should never be willingly disturbed.

WILLIAM H. ROSS.

DR. W. E. FORD

Dr. Willis Ellard Ford, one of the prominent physicians of Utica, died in his home on January 30, aged 81 years. Dr. Ford began his medical career as a member of the staff of the Utica State Hospital from 1873 to 1878. He was made medical director of St. Luke's Hospital, Utica, in 1882, and was instrumental in making it a home-like institution, to which the people of Utica gladly came. He also established the school for nurses in the hospital He was widely known as a gynecologist and as a teacher in electro-therapeutics. He was a medical leader and active in social and civic affairs, and was universally respected.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago.

Recognition of Cults.—The first annual meeting after the reorganization of the Medical Society of the State of New York, was held in Albany, N. Y., January 30 and 31, and February 1, 1906. This Journal for March, 1906, contains the addresses commemorating the reorganization, including one by Grover Cleveland.

St. Clair McKelway, Chancellor of the Regents of the University of the State of New York, discussed the recognition of cultists and said:

"The whole situation grows out of the State's assumption of the conditions to determine both preliminary and final educational tests in medicine and in surgery, in lieu of leaving, as in the past, the determination of them to the different, and to the differing, medical schools themselves, which were unable to agree upon them. It is natural for those benefited by present conditions to wish to retain them and to prevent others from sharing with them. It is natural for those who would also share them, but who do not, to try to obtain them. The Board of Regents is thus beset both by the privileged and by the unprivileged. It is made very conscious of the existence of both and of its own bombardment by both. We shall never presume the State will reduce its preliminary educational tests. As already frankly stated, we do not believe the State should, nor can we presume the State will, reduce its final professional educational tests. It should require everyone to know the how and the why and the effect and the purpose of what he proposes to do, and should then allow him medically to do nothing else, under State auspices. Frankly, should the State do less than that, the Board of Regents could well ask the Legislature to relieve it from all the medical work delegated to it, and unasked by it. Like work, however, has been delegated to us in the case of other learned professions. The improbability that the State will lower its standard is as plain to us as the fact that the State should not do so."

MEDICAL PROGRESS

A Method of Inciting Incipient Movement in Weakened and Paralyzed Muscles.—Arthur E. Porrit and O. F. Guthrie-Smith describe a method which they have used successfully in cases of anterior poliomyelitis and spastic paralysis, and in the restitution of movements in a fractured limb. The method aims to eliminate all checks to the activity of the weakened muscles by counterbalancing the weight of the limb, inducing relaxation of the opponent muscles, and finally counteracting almost entirely inertia, friction, and gravity. This allows the feeble minimal efforts of the affected muscles to act, not in the stationary limb, but in association with pendulum movements, maintained by the operator at first and later by the patient. The apparatus necessary for this purpose is an overhead bar with ball-bearing pulleys, through which run adjustable ropes and slings. By this means the faintest return of power is allowed free play, the activity of the muscle contributes to its more rapid recovery, and the patient, persuaded by the wide range of movement into thinking that he is accomplishing more than is actually the case, is encouraged to exert every effort without the usual fear of pain. The limb is hung from the bar by adjustable slings, and is then gently swayed up and down, from side to side, or back and forward as the particular case demands, all opposing forces being counterbalanced as exactly as possible. The relaxation treatment encourages a mental and a local physical condition conducive to the restoration of normal function in the affected part by instilling into the patient the necessity and ability to rest the cerebral processes and to develop a "plastic mind." The possibility of producing a maximal movement with a minimal muscle effort lessens the risk of fatigue in a weakened muscle group. — *British Medical Journal,* January 10, 1931, i, 3653.

The Pursuit of Health.—Robert Hutchison agrees with G. K. Chesterton that "of all things human the search for health is the most unhealthy." The reason is that fussiness about health increases fear and impairs the serenity which is the basis both of health and happiness. Over-anxiety concerning health may show itself as individual hypochondriasis, as vicarious hypochondriasis — when a normal person is over-anxious in regard to the health of those near and dear to him, or it may assume an epidemic form, involving whole communities—national hypochondriasis. Individual hypochondriasis is shown in its most typical form by the man who has a conviction that he suffers from some disease. In its extreme manifestation the condition may lead to fixed delusions and even end in insanity. Other types of the individual hypochondriac are the diet faddist, the man with an undue fear of disease or of microbes and the exercise crank. The scientific truth about diet put briefly is: eat moderately, taking an ordinary mixed diet, and don't worry about anything else. Likes and dislikes, however, should be listened to; they are nature's indication of what probably agrees or disagrees. It may be doubted whether a maximum degree of physical development—the sergeant's ideal—is good for health, and there is certainly no reason to believe that athletes are particularly healthy or long-lived persons.

Examples of vicarious hypochondriasis are parents who are overanxious about the health of their children and children in regard to the health of aged parents. The morbid dread of infection and the morbid care that is taken to shield children from having the usual infectious diseases of childhood at the proper time, from 5 to 10 years of age, is having a bad effect. At that time they are less dangerous than if they are postponed to late childhood or adolescence. Do not worry too much about the health of your children. Give them happy homes, the companionship of other children, plenty of plain, simple food; do not take too much notice of them, thereby creating in them vanity and self-consciousness, send them early to bed and leave the rest to chance.

Hutchison, discussing national hypochondriasis, scores health propaganda. There is, he says, a good deal of nonsense talked about detecting the beginnings of disease. Most diseases cannot be detected early, or, if they are, little can be done to stop them unless one is prepared to give up for life all that makes life worth living. Health propaganda is based on two fallacies, one that health is difficult to attain and keep and the other that it can be gotten by following certain rules. Moderation is the universal secret of health, but an occasional departure from the strict rule of moderation is probably beneficial as regards health. What we want for the attainment of health is a change of heart. Catch phrases such as "A nation's health is a nation's wealth" are cant. A nation's greatest asset is character.—*Canadian Medical Association Journal,* January, 1931, xxiv, 1.

Treatment of Erysipelas by Subcutaneous Injections of Milk.—J. Chalier reports in the *Journal de Médecine de Lyon* of December 5, 1930, that for over 7 years he has been using subcutaneous injections of milk in his erysipelas cases, more than 1,000 of which have been subjected to this treatment. The results have on the whole been quite favorable, the temperature as a rule dropping 1 or even 2 degrees on the morning following the first evening injection, with complete apyrexia by the fifth day if the injections are begun early, that is, within 12 to 24 hours of onset of the disease. Other general symptoms, such as nervous phenomena and delirium, disappear rapidly in the majority of cases. Local effects are still more striking, the erysipelatous plaque frequently changing its appearance from the time of the very first injection, becoming less tense, losing its puffiness and its dark color, with pain on pressure considerably diminished. It ceases to spread and retrogression may set in at once, but oftener this occurs after the second injection. Three or at most four injections are given, of 10 c.c. each in adults and 2-5 c.c. in children. Usually the first injection is the most active, and if it proves of doubtful efficacy, subsequent ones are likely to be futile. Typical cases have been observed in which cure was complete in 2 to 4 days, but the average course of the disease is 6 days after the injection. Treatment begun after the fourth day is useless. Relapses are observed in not over 2 to 3 per cent of cases. Suppurations are favorably influenced and their duration is shortened. The milk is filtered and boiled 20 minutes, after which the injection, preferably subcutaneous though it may be intramuscular, is made on the abdomen or the outer surface of the thigh. Local and general reactions occur, but no abscess or anaphylactic shock has ever been observed. Treatment is contra-indicated in tuberculosis, in uncompensated cardiac cases, and in hepatic alcoholics. Chalier has obained three cures in new-born infants—a remarkable record in view of the known fatality of this type.

Chronic Tonsillitis and Its Sequels.—Among the so-called "sequels" of tonsillitic foci, says O. Bruns, belong particularly the rheumatic diseases, in which class may be counted such conditions as polyarthritis rheumatica, chorea, infectious cardiac diseases, nephritis, and the so-called infectious arthritides. But every internist knows that chronic tonsillitis may be closely related causally to a whole series of disorders of the internal organs in which patients suffer with slow fever of unknown origin, with chronic septic conditions or endocarditides, subacute joint rheumatism, and recurrent attacks of nephritis which defy every kind of treatment until the removal of quite innocent-looking tonsils puts an end to their symptoms. It is difficult to produce statistics to show the extent to which tonsils are responsible for these various conditions, since all of them may result from other foci of infection. The failure of a patient to recover from disease of an internal organ after tonsillectomy is no proof that there was not a causal relation between the tonsils and the condition of the organ, for a metastasis may have taken place before the tonsils were removed, and this may have taken over the role of the excised primary focus; or irreparable anatomical injury may have already occurred before the tonsillectomy. However, all internists are of one mind that the mere diagnosis of chronic tonsillitis does not of itself justify tonsillectomy. A real and not merely hypothetical connection must be shown between the tonsillitis and the secondary disease. Operative intervention is always to be advised when there is a special tendency of the tonsils themselves to disease with ever-recurring attacks. Similarly a tendency to relapse of internal diseases suggests the desirability of removal of the tonsils. The temporary lighting up of secondary diseases upon squeezing out of the tonsils, and markedly upon operative procedure, can as a rule be noted, but these phenomena cease in most cases after a short time. With most other internists Bruns takes the view that tonsillectomy should not be carried out until from 4 to 6 weeks have elapsed since acute symptoms of disease have abated. It cannot be denied that too early operation has resulted in exacerbations of arthritis, sciatica, nephritis, and the like, which were very serious in their duration and extent.—*Deutsche medizinische Wochenschrift*, December 19, 1930.

Experimental Cancer Research.—Reviewing cancer research during the past thirty years, William H. Woglom finds the situation grave, yet not hopeless. This period of time represents one per cent. of the three thousand years during which cancer has been under observation; certainly the information gained during the thirty years represents more than one per cent. of our knowledge of cancer. Though no cure for cancer has been found, a surprisingly large amount of information has been gathered. Soil, climate and diet have been eliminated as causes of cancer, and civilization as a cause may now be disregarded. The one possible cause that has withstood critical examination is chronic irritation. During the first ten years of the thirty year period the limits within which malignant tumors can be transplanted had been mapped out, a method of protecting against their inoculation found, the resistance

of the cancer cell to various agents compared, its cultivation *in vitro* begun, the hereditary nature of cancer in mice foreshadowed, and a curiously interesting transmissible sarcoma of the fowl discovered. In the second decade the growth of the cancer cell was assessed, and two methods of producing tumors in animals were discovered—painting with tar and infestation of rats with *Cysticercus fasciolaris,* although it had been said that this would never be accomplished. In the third decade, still another means of inciting malignant growth was reported. Fibiger found that the stomach and tongue of rats respond to the presence of *Spiroptera neoplastica* by producing carcinoma, whereas the esophagus, invested by the same type of epithelium is exempt. Likewise in aniline dye workers the kidney and ureter escape, while the bladder suffers. These are simply examples of the many problems that cause progress in research to move slowly. A good start has been made in the study of the chemical nature of the carcinogenic agent in tar, the intensity and duration of irritation required to initiate neoplasia, the relation of age to the development of cancer, and so on, while the positions gained during the first two decades have been consolidated and extended. We are beginning to appreciate the marvellous delicacy of the adaptation between the etiological agent and the cell which is to become ultimately a cancer cell, and to realize not only that the irritation must be of a certain kind, and perhaps of a certain degree, but also that there may be more factors involved than simply chronic irritation. While it appears that the cure of Jensen rat sarcoma may be brought about by the development of immunity, there is no sign at present that immunity will ever be of any practical help. The very similarity of the cancer cell to the normal cell delays the discovery of a specific cure.—*American Journal of the Medical Sciences,* February, 1931, clxxxi, 2.

Treatment of Cancer of the Tongue.—Pierre Sebileau says in the *Bulletin médical* of December 27, 1930, that if cancer of the tongue were always topographically pure it would be one of the least evil of surgical cancers. Its tendency to spread to neighboring regions is what constitutes the gravity with which it is rightly regarded. Every cancer of the tongue which, by reason of its early stage, small size, favorable site, and autochthonous character, permits the surgeon to be certain that he can remove it by wide excision well beyond the limits of infiltrations, should be extirpated by surgical means rather than subjected to treatment with irradiation. Cancers susceptible of surgical removal are those of the apex, the anterior dorsal surface, the under surface between the apex and the beginning of the frenum, and those of the middle of the border, provided they are autochthonous. Cancers that should not be treated by surgical measures are (1) marginal cancer of the retro-uvular segment of the tongue which attack the wall of the pharynx, and which cannot be removed except by suppression of the angulo-mandibular wall; (2) dorso-basilar cancer which has reached the lateral wall of the pharynx, or widely extended cancer of the dorsum itself; (3) cancer which has invaded the floor of the mouth and penetrated the maxilla. In all these cases operation is not only excessively mutilating but also useless owing to its diffusion of the cancer. In the first case the x-ray is better than radium because it is difficult to place the needles and also because of the superior power of diffusion of the rays. Sometimes owing to the obstruction offered by the mandible to the rays, it is necessary to do a hemi-resection of the jaw to permit their application. In the second case the cancer, frequently diagnosed only at a late period, is best treated by external radium therapy or penetrating cervical radiotherapy. Radium puncture and radium tubulation are impossible without the help of mutilating surgery, which is inadvisable. In the third case no form of treatment is of any avail, since the cancer has penetrated the bone. Where the lymph nodes are affected, every suspected node should be widely removed by a sort of continuous exeresis in series that shall include the entire lymphatic group involved.

Concealed Cancer of the Tongue.—William F. MacFee, writing in the *Annals of Surgery,* February, 1931, xciii, 2, calls attention to an impressive number of failures to recognize cancer of the tongue for which the medical profession is responsible. In about 20 per cent. of cases the lesion is anatomically situated in such a way that it escapes early detection. Cancer may be overlooked because of its situation far back on the tongue, at the angulation of the lingual mucous membrane as it merges into the mucosa of adjacent structures, at the base of the pharyngeal tonsil or of the tonsillar sinus, at the lingual attachment of the glossopalatine arch, in the valleculae, or at the epiglottic fold. Again, it may escape detection because it is almost completely buried in the substance of the tongue. This type is nearly always in the posterior half or two-thirds of the tongue. With cancer in this location three early and important symptoms are: (1) pain in and about the ear; (2) Motor disturbances, such as disability in swallowing, in dislodging particles of food, and clumsiness in speech, and (3) painless sensory disturbances. Other hints of the presence of cancer are the following:

(1) When the patient protrudes the tongue far out it tends to deviate slightly toward the side of the lesion. (2) Often a slight dimpling, furrowing, flattening, or other evidence of retraction of the surface mucous membrane may be seen. (3) Occasionally it may be possible to detect a slight defect in the patient's speech. (4) Inspection may reveal a minute ulcer at the most superficial point of an infiltrating cancer. (5) Palpation properly carried out will nearly always reveal an area of induration, and should not be omitted in making an examination of the tongue. If an indurated area is discovered, the possibility of cancer should be seriously considered.

Primary Cancer of the Thymus.—L. D'Antona and G. Buonamini, writing in the *Riforma medica* of November 17, 1930, say that primary cancer of the thymus is seldom diagnosed during the life of the patient. In a personal case which they report their diagnosis was metastatic cancer of the liver probably from a primary tumor of the stomach. There was no indication of any lesion of thymus or mediastinum, nor had the patient suffered with cough, pains, or sense of oppression in the retrosternal region. On the other hand there had been symptoms in the digestive organs, notably an absence of hydrochloric acid secretion by the stomach and the fact of two serious intestinal hemorrhages. At autopsy a tumor the size of a hen's egg was found on the internal surface of the apex of the left lung, strongly projecting, of a hard consistency, even bony in spots. Scattered throughout the liver parenchyma were neoplastic nodules. The mediastinal tumor was composed of large, irregular fibrous cords anastomosing with one another, made up of a tissue abounding in cells and containing necrotic areas here and there, in course of hyaline transformation and calcification. This was evidently the neoplastic parenchyma. In some places, toward the center of the cords, there were large masses of uniformly granular detritus with formations strongly resembling Hassall's corpuscles. While the cells composing the cords contained neither secretory products nor drops of fat or lipoid substances, the latter appeared in great abundance in the necrotic masses at the center of the largest cords. Where the cords showed a tendency to infiltrate into the pulmonary tissue there was less differentiation between an external zone abounding in lymphocytes and a central zone of epithelioid character. The enlarged retroperitoneal glands were infiltrated with a tissue very similar to that of the intrapulmonary neoplastic cords. The nodules of the liver were composed of irregular cellular cords at the center of which were granular necrotic masses abounding in fat and lipoids. There was no question that the neoplastic growth here was a secondary invasion from that in the apex of the left lung. The small size, the consistency, and the localization of the primary growth differ somewhat from the classic descriptions in the literature.

Nerve Hyperplasia in Chronic Inflammation.—M. Favre and J. Dechaume point out that the changes undergone by the nervous system of an organ altered by chronic inflammation have not received enough attention from investigators. They have recently been studied by a number of authors in neurogenous appendicitis, in chronic ulcers of the stomach and in sclerocystic ovaries. Favre and Dechaume are now able to demonstrate that such changes exist also in glandular parenchyma. In the course of chronic pancreatitis and hepatitis they observed that sclerosis existing side by side with epithelial reconstruction of an adenomatous course, and with muscular regeneration of myomatous appearance, was accompanied by an indisputable nerve hyperplasia. The abnormal number of nerve fibers, their irregular size, the variety of their direction and, most of all, the topographic anarchy of the neurites visible on certain slides, could be due only to a proliferation whose expansion was bridled—*i.e.*, only to an abnormal regeneration. These observations justify the assertion that nerve hypergenesis is a reality in certain chronic inflammations of glandular parenchyma. A large proportion of these hyperplasias must be regarded as regeneration neuromata, which may be likened to amputation neuromata of the peripheral nerves or to postoperative cicatricial neuromata. Some neurites are centainly sectioned, whether in the course of acute inflammation, or by sclerosis and by the muscular hyperplasias which develop in the vascular wall. The view that the central end of the neurite is capable of proliferating into vascular adventitia altered by perivascularitis is well justified by the facts, for in several cases veritable ischemic sequestra were found with "shadows" of necrotic nerve fibers side by side with vestiges of vessel walls, their underlying central end only awaiting the development of replacement sclerosis to proliferate. The question arises as to how far this anarchic change of the nervous system plays a part in the mysterious process that links chronic inflammation to cancer. On the other hand, these neuromata constitute in the organs local irritative spines which may modify the functioning of the parenchyma that has been spared by the inflammation and may later create painful disorders and functional reflexes.—*Journal de médecine de Lyon,* December 20, 1930.

LEGAL

THIS YEAR'S CHIROPRACTIC BILL

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

The perennial chiropractic bill has made its appearance before the Legislature. Once again the Legislature of the State of New York is asked to put its stamp of approval upon a bill which seeks to legalize and sanction a cult of quacks. Once again the chiropractors, whose practices have time and again been declared by our courts to be a violation of the law, are seeking legal sanction for their unfounded and unscientific practices. A brief statement of some of the provisions of the bill in question (Senate Introductory No. 361, Assembly Introductory No. 636) is sufficient to demonstrate its objectionable features.

The bill defines the practice of chiropractic as "diagnosis, the palpating and adjusting by hand of the vertebral column and tissues. This shall not include the use of operative surgery or obstetrics or the administering or prescribing of drugs or medicine included in the pharmacopœia or materia medica." Of course this is a clear attempt to change the statutory definition of the practice of medicine which has been in force upon our statute books for twenty-four years. The practice of medicine is defined in Section 1250, subdivision 7 of the Education Law as follows:

"A person practices medicine within the meaning of this article, except as hereinafter stated, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition, and who shall either offer or undertake, by any means or method, to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition."

This definition expresses what both the laity and the medical profession understand as the practice of medicine. Our present statute further provides that a person who unlawfully practices medicine is guilty of a misdemeanor. It has been repeatedly held by our courts that a so-called chiropractor who plies his calling, but who has not been admitted to practice medicine, is guilty of a crime and many such chiropractors have been prosecuted and convicted.

In People v. Ellis, 162 App. Div. 288, the defendant was a graduate of the Davenport University of Chiropractics. He had a sign, with regular office hours, and treated about two hundred persons for ailments of the stomach, chest or spine as well as for nervousness, hysteria and diseases coming from pressure on the nerves. It was established by the prosecution that the defendant had examined the complaining witness and pronounced her arch to have fallen, massaged the foot and advised a different shoe; and that on a further occasion he manipulated the patient's spine which, speaking as a "spinologist," he pronounced out of alignment in several places. He said that he could restore it, but it "probably would not stay the first time." He further gave his opinion that "the nerves leading to the ankle might be impinged so as to cut off the circulation." The defendant was convicted of the crime of practicing medicine without a license. In its opinion the court, among other things, said:

"Appellant's office sign, his circular and professional card, as well as his own frank admissions as a witness, all show that he holds himself out as able to diagnose, treat and prescribe for pain, disease and injury. Rubbing and pressure on the human joints are old therapeutic agents. When accompanied by such attempts at diagnosis as the statement that a patient's pains in the ankle were from the spine having come out of alignment through displaced vertebrae, appellant's acts come within the statutory definition of the practice of medicine."

The increasing vigilance of those to whom is entrusted the task of prosecuting these violators, and the opinions of our courts which have time and again held the chiropractors to be violating the law, make apparent the reasons which prompt the chiropractors to seek to legalize the practice of chiropractic and to declare without the definition of the practice of medicine "diagnosis, the palpating and adjusting by hand of the vertebral column and tissues."

The bill further provides that within thirty days after this article takes effect, the regents shall appoint a board of examiners consisting of three members all of whom shall be chiropractors, and that no medical doctor or osteopath shall be eligible for appointment on the board at any time.

The bill also provides as follows with respect to present practitioners:

"The regents shall issue a license to such persons who are certified by the board to be twenty-one years of age, citizens of the United States or who have declared intention of becoming such citizen, of good moral choracter, and to have passed a special examination before the board, in

anatomy, physiology, symptomatology, including diagnosis of communicable diseases; hygiene and the theory and practice of chiropractic, such examination being to determine whether the applicant has a general knowledge of the practical application of such subjects in the practice of his profession and who within six months after the appointment of the board by the regents made application to the board in writing accompanied by a fee of twenty dollars, and to be otherwise qualified in any one of the following:

"(a) Graduates after a resident course of four or more school years of six months each, or twenty-four months altogether in a school teaching chiropractic, who during the period of one year immediately preceding and at the time of taking effect of this article shall have been actually engaged in the practice of chiropractic in this state.

"(b) Graduates after a resident course of three or more school years of six months each, or eighteen months altogether, in a school teaching chiropractic, who, during the period of three years immediately preceding and at the time of taking effect of this article, shall have been actually engaged in the practice of chiropractic in this state.

"(c) Graduates after a resident course of two or more school years of six months each or twelve months altogether in a school teaching chiropractic, who, during the period of nine years immediately preceding and at the time of taking effect of this article, shall have been actually engaged in the practice of chiropractic in this state.

"The board may in its discretion, accept as the equivalent for not more than one-half of the educational requirements of subdivisions (b) or (c) of this section evidence of fifteen or more years of reputable practice.***"

But, how could the board in its discretion accept as the equivalent for not more than one-half of the educational requirements of subdivisions (b) or (c) of the section above referred to, fifteen or more years of "reputable practice"? By what process of construction fifteen years of lawbreaking can be transformed into fifteen years of "reputable practice" is not explained in this bill. For twenty-four years a person engaged in the practice of chiropractic in this state has been guilty of a crime, but according to the provisions of this bill the chiropractors are changed from lawbreakers into reputable practitioners.

The bill further provides that the regents may, if approved by the board, waive the examination of any applicant for license who presents satisfactory proof that he has been duly licensed by examination as a practitioner of chiropractic in any other state of the United States having licensing requirements equal to New York State; upon such waiver and the payment of the fee of twenty-five dollars the regents may issue to him a license to practice chiropractic.

It is further provided by the terms of the bill that "Each duly licensed practitioner who shall have complied with the provisions of this article shall have the right within this state to practice chiropractic as defined in this article, and shall be subject to all disabilities, limitations and restrictions and entitled to the same rights, privileges and immunities imposed upon and granted to all professional persons by the civil practice act and judiciary law."

Among other things, the bill provides under the heading "Present Practitioners" that "Evidence of the course of study, the name and location of the school or college, the subjects required in the resident course at the time for graduation, that the applicant completed said course, age and *period of practice of each applicant*" under the subdivisions of this article relating to the practice of chiropractic in this state "shall be given by the affidavit of the applicant filed with the board"; and *"proof of the good moral character of such applicant shall be made by the affidavit of two reputable citizens."* How any reputable citizen could make an affidavit that a person who openly and wilfully has been violating our statute which defines the practice of medicine, is of good moral character, this bill does not say.

Of course the educational requirements in this bill are meagre indeed, and it is interesting to contrast the educational requirements for chiropractors in this bill with the requirements for those seeking a license to practice medicine.

When bills of this character make their appearance in the Legislature, we feel that it is particularly pertinent to quote the language of the United States Supreme Court, the highest court in the land, in the case of Dent v. West Virginia (129 U. S. 114):

"Few professions require more careful preparation by one who seeks to enter it than that of medicine. It has to deal with all those subtle and mysterious influences upon which health and life depend, and requires not only a knowledge of the properties of vegetable and mineral substances, but of the human body in all its complicated parts, and their relation to each other, as well as their influence upon the mind. The physician must be able to detect readily the presence of disease, and prescribe appropriate remedies for its removal. Every one may have occasion to consult him, but comparatively few can judge of the qualifications of learning and skill which he possesses. Reliance must be placed upon the assurance given by his license, issued by an authority competent to judge in that respect, that he possesses the requisite qualifications. Due consideration, therefore, for the protection of society may well induce the State to exclude from practice those who have not such a license, or who are found upon examination not to be fully qualified."

This bill, and others of similar character which

may be introduced in the present session of the Legislature, should and will be vigorously opposed not only by physicians but by every citizen of our State who is interested in maintaining and preserving the wise and salutary restrictions which the law has imposed upon the quacks, cultists and those who seek to prey upon the public health and to menace the lives and limbs of the credulous and the unwary. What was said in this column a year ago with respect to the chiropractic bills which were then before the Legislature, is worthy of repetition at this time: "It would seem that the Legislature, which has so often set its face against these preposterous licensing measures, should not again be troubled with the insolent demands set forth in this bill."

CLAIMED NEGLIGENCE IN TREATING TUMOR DURING PREGNANCY

In this case a woman consulted the defendant doctor complaining of irregular menstruation, stating however that she was not pregnant as it would be impossible for the reason that she had used contraceptive precautions. An examination by the doctor revealed a uterine fibroid tumor about the size of a small orange. The physician advised *x*-ray treatments, and the patient was told that such treatments given for fibroid uterus might produce artificial menopause, but she consented to undergo the treatments and received eleven *x*-ray applications over a period of three months.

About six weeks later a radiographic examination of her abdomen showed a fœtus which appeared to be normal and about six weeks of age. Two months later the patient was delivered prematurely of a poorly developed child weighing about three and a half pounds. The delivery was unusual only in the fact that the time of labor was extended about forty hours, which was due to a rupture of the water-bag, resulting in a dry birth. After the childbirth, the patient suffered from high temperature, chills and pains in the stomach other than after-pains. At birth the child was not deformed, but a few days thereafter developed marked hydrocephalus. Five months after the birth of the child, the patient resumed menstruation and thereafter was apparently in normal condition.

Suit was subsequently instituted against the physician, in which it was claimed that he had negligently failed to discover the plaintiff's condition of pregnancy and improperly undertook to treat her for a fibroid tumor, and that the administering to the plaintiff of *x*-ray treatment permanently impaired her health. It was also claimed by the plaintiff in her bill of particulars that the *x*-ray treatments had made her sterile and had caused an abnormal birth and infection in the intestines and an acid or unhealthy condition of the uterus. The case was duly brought on for trial and just as the defendant was ready to proceed, the plaintiff's attorney announced that he was not ready to go ahead with his case. The court thereupon granted the defendant's motion to dismiss the complaint, thus terminating the matter in favor of the doctor.

CLAIMED NEGLIGENT USE OF X-RAY

In this case a young lady while working in a textile mill swallowed a piece of machine needle accidentally. Not until a week later did she complain to her employer and he sent her to the defendant doctor for treatment as a compensation patient.

The doctor was very doubtful as to the possibility of determining the location of the needle. The patient informed the doctor that a few days after swallowing the needle she had had pain in her chest. The doctor took an *x*-ray picture at the spot indicated by the patient where the pain had existed. No foreign body appeared on said *x*-ray picture and therefore others were taken at points higher and lower, which showed nothing. The technique used in taking said *x*-ray pictures was in all respects in accordance with customary practice.

Subsequently the patient complained that a burn developed on her chest at the point where the *x*-rays were taken and that a bad condition of ulceration had developed at that point. She complained that the burn was very painful and it caused her to be lame in her arms and sides.

Thereafter the doctor was sued for damages sustained, on the ground that he had been negligent in operating the *x*-ray machine.

On the eve of trial the plaintiff's attorney expressed his inability to proceed with the case and therefore voluntarily discontinued the action against the doctor.

NEWS NOTES

COMMITTEE ON PUBLIC RELATIONS

The regular monthly meeting of the Committee on Public Relations was held in the New York Academy of Medicine, with all the members present, and also Dr. Joseph S. Lawrence, Executive Secretary of the Committee, and Dr. Frank Overton, Executive Editor of the NEW YORK STATE JOURNAL OF MEDICINE. Several members of the executive committee of the Council dropped in at the Committee's Luncheon, which was served at one o'clock.

The Committee first discussed ways for developing leaders in the county medical societies. The societies which are most successful are those which have outstanding leaders who continue active year after year. Leadership in forming contacts with official boards and lay organizations is a question of temperament largely Some doctors delight in making the public contacts, and it is these who are valuable as leaders of the public relations movement in the counties.

It is the aim of the State Committee on Public Relations to discover the local doctors who have a natural aptitude for making contacts with health organizations. The State Committee will instruct the chairman and members of local committees, and will inform them what the leaders in other counties are doing to secure the cooperation of all organizations and committees in the counties.

The State Committee has been handicapped by a change of chairmen and personnel of the county committees in the new year; and it voted to get out a blank form to be sent to each county so as to record the chairman and members of its public relations committees. Better still, of course, would be to discover the best men and then to retain them in their positions year after year.

Methods of informing and instructing the chairmen and members of the local committees were also discussed. While the reports of the activities of the State Committee have been published regularly in the Journal, yet some members and even chairmen have said that they are not familiar with the reports. The committee has therefore prepared seven special bulletins during the past year and has sent them to the chairmen of the county committees and the officers of the societies,—a list of about 250 names. The bulletins have sometimes been reprints of articles and editorials which have appeared in the Journal, and sometimes they have been on special subjects not previously reported. It is the intention of the State Committee to stimulate the local committeemen to read every issue of the Journal, with care, paying special attention to the items relating to public relations.

The surgical service of the new hospital of Lewis County was discussed. Two plans had been suggested. One was that the doctors of the county should secure surgical consultants and operators from Watertown or Syracuse, or other center, as occasion might arise; and also to appoint several surgeons on a consulting staff whose members would be available on call.

The other proposition was that a surgeon be invited to open an office in the hospital, rent free, on condition that he should be available for all emergency service, but should be permitted to do private practice.

The decision between these two plans is of importance, since the State of New York will pay half the cost of maintaining the hospital, and the rules regarding its conduct must be approved by the State Commissioner of Health. The consensus of opinion of the Committee on Public Relations was that the local doctors of Lewis County should get together and decide for themselves between the two plans; but with the understanding that they can always secure the advice and assistance of the Committee.

The administration of the County Welfare Law was next discussed. Dr. W. H. Ross, President of the State Medical Society, told of the excellent operation of the law in every county in which a representative committee of the County Medical Society had conferred with the County Welfare Commissioners. Dr. Ross himself was chairman of a committee of the Suffolk County Medical Society which had gone to the Welfare Commissioner and presented the point of view of the doctors. The Commissioner said that the doctors had been demanding conflicting methods and charging various prices; and he promised that if the doctors themselves would decide on standard plans and fees, he would adopt them. The Commissioner agreed that when an emergency occurred, he would approve the bill of the doctor for treating the case for forty-eight hours; but that the doctor should report the facts to him within that period, and secure his authorization for further treatment.

The Suffolk County Committee also secured the consent of the five county hospitals to make a uniform charge of $3.50 per day for ward cases.

Many other agreements and standards will have to be developed in Suffolk County, but the progress so far has been exceedingly pleasing to the Commissioner and to the physicians.

The variation in the charges made by the hospitals in a County have led to misunderstandings, as in an up-State County, in which there are five

hospitals, one charging $4.50 per day, another $3.00 and the third, $2.29 per day in the public ward, thus leading to embarrassment as to which hospital to patronize. The evident remedy would be that the hospital managers agree on a uniform scale of charges.

Such conditions as these are those with which the local committees are best fitted to deal.

Dr. O. W. H. Mitchell reported that a national conference on college health will be held in Syracuse from May 4 to 9, at which three hundred delegates were expected. Dr. Mitchell invited the members of the Committee to attend the conference and take part in its deliberations.

The Committee also considered several questions of a somewhat confidential nature, such as threatened disputes, in which the assistance of the members is desired. One of the most gratifying features of the work of the State Committee is the spirit of goodwill with which its offers of help are accepted by the county societies and other local organizations.

LEGISLATION

LEGISLATION BULLETIN NO. 3, FEBRUARY 4, 1931

No action has been taken on any of the bills which we have already reported, except the transfer of the Hastings liquor bill to the Committee on Finance.

A hearing has been announced for the anti-vivisection bill before the Assembly Committee on Codes, on Tuesday, February 24th, at 2:00 P. M.

A few bills were not reported in the last bulletin that should have been. They will be named below in connection with others which have been introduced during the week:

Senate Int. No. 53-Downing (Assembly Int. No. 344-Livingston), amends the Compensation Law by providing that only the state fund, a county, city, village or other political sub-division shall be insurance carriers under the law, stock corporations and mutual associations being eliminated. This bill was before the legislature last year and has the strong support of labor. It is our impression, however, that physicians have frequently found settlement with the state fund more difficult than with other insurance companies. This condition is particularly true in upstate sections. Is our impression correct? Is it, in your opinion, desirable that the state fund should supplant other insurance companies in compensation work?

Senate Int. No. 178-Love. (Assembly Int. No. 236-Esquirol), amends the Workmen's Compensation Law by providing compensation shall be payable for disabilities or death of an employee resulting from any occupational disease. There are now four bills to this point before the legislature.

Senate Int. No. 211-Mastick, amends the Workmen's Compensation Law by providing compensation for all diseases arising out of employment. This bill was before the Senate last year. The committee has considered the bill and has decided that it will not place opposition to it this year.

Senate Int. No. 345-Cilano (Assembly Int. No. 441-Esmond), amends the Criminal Code authorizing the court to appoint psychiatrists or mental experts to examine certain defendants. This bill was before the legislature last year and is a companion bill to Senate Int. No. 344-Cilano (Assembly Int. No. 442-Esmond), which provides for certification of qualified psychiatrists.

Assembly Int. No. 227-Doyle, amends the Penal Law by prohibiting the sale or giving away of bichloride of mercury, mercuric chloride or corrosive sublimate, except on written prescription of a physician. The committee respects the spirit back of the bill, but believes that if the object is to prevent or make it more difficult for people to commit suicide, many other poisons should be included, and is of the opinion that regardless of this law, these preparations would be available without securing them from a physician.

Assembly Int. No. 276-Sheldrick would amend the Public Welfare Law by providing old age relief shall be given at age 65 instead of 70 as at present. This notice is given for its informational value and not because the amendment would have any effect upon the practice of medicine.

* * * * *

Senate Int. No. 377-Campbell (Assembly Int. No. 531-Hewitt), would amend the County Law by giving the coroner a fee of $1.00 for reporting to motor vehicles commissioner concerning a death found to have been the result of a motor vehicle accident. Referred to Internal Affairs Committee.

Senate Int. No. 385-Love, would amend the Public Health Law by providing every certificate of birth shall contain photograph of finger prints of mother and foot prints of child. Referred to the Health Committee.

Senate Int. No. 441-Hickey, would amend the Education Law to permit employment of optometrists and oculists for examining children in public schools. Referred to the Education Committee.

Senate Int. No. 447-Love, would amend the Workmen's Compensation Law by adding to list of occupational diseases for which compensation

is payable all disabling diseases and disabling illnesses. Referred to Labor Committee.

Assembly Int. No. 573-Dickey, would amend the Health Law, making it a violation of article to possess pipes, lamps and other apparatus for the use of opium. Referred to the Health Committee.

Assembly Int. No. 574-Dickey, adds new section to the Health Law, making it a violation of article to obtain habit-forming drugs from one physician while receiving treatment from another without disclosing the fact. Referred to the Health Committee.

Assembly Int. No 584-Moffat, would amend the Workmen's Compensation Law by providing for compensation for all occupational diseases arising out of employment. Referred to the Labor Committee.

Assembly Int. No 605-Swartz, would amend the Judiciary Law so as to exempt from jury duty registered physiotherapists. Referred to the Judiciary Committee

Assembly Int. No. 636-F. L. Porter has introduced the chiropractic bill which was reported before as introduced in the Senate—Int. No. 361-McNaboe. Referred to the Education Committee.

LEGISLATION BULLETIN NO. 4, FEBRUARY 11, 1931

For the benefit of those who could not attend the conference of Chairmen of Legislative Chairmen of the County Societies yesterday, let us report that the following thirty-three counties were represented:

Albany	Greene	St. Lawrence
Allegany	Monroe	Schoharie
Bronx	New York	Seneca
Chautauqua	Oneida	Steuben
Clinton	Onondaga	Suffolk
Cortland	Ontario	Tompkins
Erie	Orange	Warren
Essex	Orleans	Washington
Franklin	Queens	Wayne
Fulton	Rensselaer	Westchester
Genesee	Richmond	Yates

In addition to these, there were present, also, Drs. Aranow and Rainey of the State Committee; Drs. Ross, Johnson, Shaw, James N. Vander Veer, Overton; Dr. Sweet, chairman of the Medical Research Committee, and Mr. Clearwater, our attorney. The guests were Commissioner Parran and Deputy Commissioner Brooks, from the Department of Health.

The bills which you have received from time to time were considered, with the following results:

Approved

Senate Int., No. 594-Love, providing a threefold damage for injuries caused by the unlawful furnishing, supplying or administering of dangerous drugs or medicines.

Assembly Int. No. 52-Horn (Late Print No. 514), to amend the Workmen's Compensation Law in relation to the allowance of claims for medical and surgical treatment.

Assembly Int. No. 574-Dickey, to amend the Public Health Law in relation to obtaining drugs from one physician while receiving treatment from another without disclosing the fact.

Opposed

All Workmen's Compensation bills providing for the unlimited extension of compensable diseases. Not opposed to the specific increase in the list of compensable diseases.

Senate Int. No. 86-Love, amending the Penal Law in relation to mixing babies.

Senate Int. No. 361-McNaboe, to amend the Education Law in relation to the practice of chiropractic.

Senate Int. No. 385-Love, to amend the Public Health Law in relation to contents of certificate of birth.

Senate Int. No. 441-Hickey, to amend the Education Law in relation to employment of optometrists and oculists for the examination of children in public schools.

Assembly Int. No. 5-Cuvillier, compulsory health insurance.

Assembly Int. No. 227-Doyle, to amend the Penal Law in relation to preventing accidental poisoning by bichloride of mercury and compounds thereof and regulating the sale and manufacture thereof.

Assembly Int. No. 143-Vaughan, anti-vivisection bill.

Assembly Int. No. 817-Story, to amend the Penal Law in relation to clinics in hospitals supported wholly or partly at public expense.

* * * * *

In view of the fact that we have been informed there is a great demand upon the printers of legislative bills for copies of the Cuvillier health insurance bill and compensation bills which increase the number of compensable diseases and conditions, particularly the Mastick bill, a good deal of time was spent in discussing them. It was brought out during the discussion that the particular step the medical men should take is to secure a medical advisory council in the Department of Labor, in order that medical men may discuss directly with the Commissioner of Labor the problems that are arising at present and will be many times multiplied if the contemplated legislation is enacted into law. Dr. Flynn, from the

Bronx, correctly characterized such an advisory board as a "grievance board," and in his opinion it should be compensated for the services it will be obliged to render. The conference unanimously endorsed the idea of the creation of a medical advisory council in the Department of Labor and asked that either last year's bill be reintroduced or modified as Dr. Flynn might suggest.

The hospital licensure bill was also discussed and there was a unanimous request that the bill as finally revised be reintroduced this year.

Since our last bulletin the following bills have been introduced:

Senate Int. No. 580-Love, amends the Penal Law to make penalty for having narcotics in possession, imprisonment for not less than five nor more than ten years, instead of not more than ten years as at present. Referred to the Codes Committee.

Senate Int. No. 594-Love, provides for threefold damage for injuries caused by unlawful furnishing, supplying or administering dangerous drugs or medicine. Referred to Codes Committee.

Dr. Love has had these two bills before the legislature in other years.

Senate Int. No. 648-Baxter, amends the Public Health Law by providing for excluding from school, children not vaccinated, whenever smallpox exists in a school district, for a period of 14 days, such period to be extended for another 14 days if new cases of smallpox continue to develop. Referred to the Health Committee. This is a new form of the anti-vaccination bill.

Assembly Int. No. 786-Coughlin, amends the Workmen's Compensation Law to permit injured employee to recover reasonable amounts expended for medical or other attendance.

Assembly Int. No. 817-Story, amends the Penal Law providing no hospital supported wholly or partly at public expense shall charge for medical services given while operating a clinic to which public is invited. Referred to the Codes Committee.

Assembly Int. No. 980-Story, amends the Workmen's Compensation Law by striking out list of occupational diseases and providing compensation shall be payable for any occupational disease or illness which it shall be established by medical testimony was directly due to or caused by any employment enumerated in sub-division one. Referred to the Labor Committee.

* * * * *

Now is the time to make an appointment with your Senator and Assemblymen to discuss these bills. The Commissioner of Health told us yesterday that the Governor expects to hand the legislature a report of the commission he has had studying public health activities in the state, next week. Some legislation will arise from that report, undoubtedly.

February 18, 1931

Senate Int. No. 648-Baxter, would amend the Public Health Law so as to abolish compulsory vaccination of school children. Vaccination would only be required of school children when the Commissioner of Health would certify that smallpox exists in that school district and then only of those children who wished to continue attendance at school. If the parents do not wish to have their children vaccinated they can exclude them from school for a period of 14 days, but if other cases appear at the end of that time they would be obliged to remain away another period or more of 14 days. It would seem to us that the author has missed the point that vaccination is intended as a protection of the public, and to disbar children from school and not vaccinate them would contribute but very little toward the prevention of the spread of the disease.

Senate Int. No. 741-Hastings, would create a temporary state commission to make a study and investigation of the economic effect of sickness, etc. The spirit of the bill is probably commendatory, but an appropriation of $15,000 will not carry the investigation far.

Assembly Int. No. 980-Story, would amend the Workmen's Compensation Law in relation to occupational diseases by deleting from the law all reference to individual diseases and introducing a blanket provision. This is along the line of some other bills that you have received and the conference, in studying bills of this character, agreed that every disability —not only injuries—which the employee suffers because of his occupation, should be compensated; but a blanket provision such as this is sure to produce difficulties for the examining physician.

Assembly Int. No. 991-Coughlin, would amend the General Municipal Law in relation to supervision of the treatment of the indigent ill. In our opinion there is no need for this bill; everything that it advocates can be done under the existing law.

HARRY ARANOW,
WALTER A. CALIHAN,
JOHN J. RAINEY,
Committee on Legislation.

THE COMMITTEE ON HEALTH EXAMNATIONS

THE CHAIRMAN'S MESSAGE

Our purpose is to get the citizens of the State to report to the physicians' offices for health examinations.

We are beginning with the women. We have the official endorsement of the greatest two organizations, the General Federation of Women's Clubs and the Parent-Teacher Association.

In the General Federation of Women's Clubs there are six hundred local clubs of women Their attention is concentrated, this year, on three health matters,

1. The County Health Unit.
2. Measles.
3. The Health Examination

The General Federation asks us to give them authoritative pamphlets on Health Examinations to send to their clubs and to provide competent and interesting medical speakers before their clubs. This is a magnificent opportunity to bring to the women of the State, sound doctrine and ethical medical guidance.

They will do their part. We must do ours We ask the physicians of the State if they want the women to come to them for examinations, to do the following:

1. Prepare yourselves to give good examinations. Ask for post-graduate instruction and articles in the medical journals; read, talk and do health examinations.

2. Send your names in to your county chairman or the state chairman to be listed to receive special aid, assistance or information.

3. Make your wishes known to your county organization and the state committee. If we broadcast on a national hookup, what would you want your patients and your prospective patients to hear? If we syndicate these talks for the newspapers, what do you want your patients and prospective patients to read?

It is estimated that over three quarters of the health examinations already done in the State are done by physicians employed by industries, organizations of various kinds and the State itself. If we are prepared to have *health examinations done in the future by the* State and the industries and not in our own offices, all we need to do is to remain apathetic and do nothing. This is the broad and easy road to professional and economic poverty.

If you want the medical profession to do this medical work in their capacity as private practising physicians,—because it is better done by us and we want to do it,—we, each one of us, must energetically go to work.

Preventive medicine will be practised. The service of preventive medicine will be given to the public increasingly every year. By whom?

C. WARD CRAMPTON, M.D.
Chairman.

MINUTES OF MEETING

A meeting of the Committee on Periodic Health Examination was held at the Society Rooms at the Academy of Medicine, New York on February 13th, 1931 at 11 A.M.

Present: Dr. C. Ward Crampton, Chairman; Dr. Nellis B. Foster; Dr. Marion C. Potter; Dr. Walter D. Ludlum; Dr. Guy H. Turrell. Dr. Thomas P. Farmer, Chairman of the Committee on Medical Education also met with the Committee on invitation of the Chairman.

The minutes of the previous meeting having been published in the Journal were dispensed with.

The chairman reported that the plan for the registration by the County Societies of physicians prepared to give health examinations proposed at the last meeting of the Committee had not been approved by the Council of the Society.

In accordance with suggestions made at the previous meeting, it was voted that an effort be made to arrange with one or more of the radio stations for a short period each week for broadcasting on the subject of periodic health examinations. All material is to be carefully prepared by various authors and then carefully correlated, censored and approved by a subcommittee before broadcasting. Dr. Potter described the successful methods being used in Rochester, and it was decided that these might well be used as a model.

It was voted to include in the letter to each county society a request for information as to the opportunities for broadcasting in the several counties, and what, if anything, was being done at present.

A sub-committee on broadcasting was appointed, consisting of Doctors Foster, Chairman, Ludlum and Crampton.

Dr. Potter recommended that the information given in each broadcasting talk be printed

and made available for distribution to those who were interested and who might apply for it. This was approved and formally adopted.

The Chairman offered the suggestion that skeleton outlines of one or more addresses on periodic health examination be prepared by the Committee—addresses suitable for use by busy doctors before women's clubs, schools, etc.

After discussion, this suggestion was adopted and the Chairman appointed a committee of one to prepare such an outline address. Dr. Potter suggested that these addresses might be supplemented and popularized by the use of a film in connection with the addresses. She suggested such films as "Working for Dear Life" and "Don't be a Goose." Dr. Turrell was appointed a committee to investigate and report on the availability of such films, their cost and how they may be obtained.

A letter was read from Mrs. Maude Burgess of the Parent-Teachers and Women's Clubs Bureau of the Metropolitan Life Insurance Company asking the following specific questions:

1. Will the State or the County Medical Societies furnish health speakers for meetings of the General Federation of Women's Clubs? To this the Committee would answer "yes," so long as the subject matter of the desired address comes within their province.

2. How may such speakers be obtained? Answer: "Through Dr. Crampton, Chairman of this Committee."

3. What literature is recommended? This question could not be answered at this meeting. The Chairman was appointed a committee to look the matter up and report.

The Chairman then presented Dr. Farmer, stating that he had asked him to meet with the Committee and that he especially wished his advice on these points.

1. The sponsoring and scope of articles on health examination to be published in the State Journal of Medicine for the information of the medical profession.

2. What committee should prepare courses of instruction in health examination for classes in the county societies.

3. The program under the auspices of the Committee at the Syracuse meeting in June.

Dr. Farmer replied that in his opinion the prosposed articles for the Journal should be prepared by or under the auspices of both Committees. He believed that the articles should be of a practical nature. He suggested as one possible subject the examination of a patient consulting a doctor for a minor ailment so as to discover significant related conditions or those of prophylactic value.

In regard to the second question, Dr. Farmer thought it was within the scope of the Committee to determine the content of the courses in periodic health examinations, and stated that after this had been done, both Committees on Medical Education would arrange the meetings and foot the bills. There was considerable discussion of the subject matter desirable for such courses and of the difficulty of making such courses attractive to the average medical practitioner. It seemed to be agreed that the courses should not invade the domain of ordinary physical diagnosis any more than absolutely necessary, but might include a simple story of what to do and how to do it with special reference to practical methods of examining a part or system and to the commonest findings in comparative health.

Dr. Potter and Dr. Calihan were appointed a committee to submit a program of subjects and methods for such courses.

With regard to the Syracuse meeting, Dr. Farmer stated that the National Tuberculosis Association was to meet in Syracuse in May, 1931, and the Association of Health Services of American Colleges and the Alumni Association of Syracuse University were to meet there early in June.

Dr. Crampton suggested that the Federation of Women's Clubs be asked to cooperate with the Committee at the Syracuse meeting.

Further discussion of the Syracuse meeting was postponed until the next meeting, which was fixed for March 13, 1931.

The meeting adjourned at 2 P.M.

GEO. H. TURRELL,
Secretary.

NEW YORK PHYSICIANS ART CLUB

Among the two hundred thousand physicians in the United States there may be found representatives who show high ability in every kind of culture and art. The recognition of the outstanding work of physicians in the graphic and plastic arts is the object of the New York Physicians Art Club, which has brought together for the fifth time the art productions of members of the medical profession. The Club is exhibiting over two hundred and fifty examples of paintings, drawings, photographs, statuary, wood carving, and metal work, in the exhibition room on the ground floor of the building of the New York Academy of Medicine, and will continue the exhibition for one month from February fourteenth, during the afternoon and evening.

In judging the exhibits, one must remember that a work is exhibited only once, and that the productions of several of the doctor-artists have already been shown in the previous four exhibits. However, a view of the present exhibit will make the visiting physician glad to see his professional brethren alert in art expression.

To judge the art works of the exhibit from the viewpoint of an artist is as difficult as it would be for the artist to judge the professional technique of the surgeon. It will therefore suffice to quote from the catalogue the words of Stephen Bourgeois, who writes as an artist:

"With a few exceptions most of the doctor-artists are in fact more interested in technic, in skill, in methods of composition or color arrangement, etc., than in actual expression, although they probably believe the contrary. Curiously enough most of them are inveterate optimists, whereas the doctor's profession would make one expect differently. With the exception of the work of one painter one cannot believe himself face to face with work done by physicians I leave it to the doctors themselves to make their own diagnosis of the case.

"The majority seems to have a marvelous time in escaping to the country, enjoying fresh air, standing their easel before a lovely corner and going to it with the use of standardized methods borrowed of some other artist. Others assemble carefully optical facts into forms in the happy hope that they assemble themselves into a concept. Unfortunately or rather fortunately art does not happen like that. It is not so complicated. It comes more simply when tackled simply As one can see from a small number of real creative pictures in the present exhibition, technic comes by itself, when the mind knows beforehand what it wants.

"There are innumerable ways of looking at things Every brain imagines differently. Since we have no more general beliefs, no general style can exist. This means the individual must express himself, and not derive from teachers. Otherwise the best talent goes wrong. The question is therefore how to release the images from the mind. For most people it is impossible to paint directly from nature without losing grip on the whole. Few see through the veil of nature the essential action behind appearances. It is much easier to paint from memory because in memory action crystallized itself with ease. There are a few crystallized ideas in painting and sculpture in this exhibition. They constitute the backbone of the show.

"The medical profession trains its members to use exclusively detached, objective observations and experiences. The same principles underlie all real results in art. If therefore the doctors apply the principles of their craft to painting and sculpture, they will be all artists and show the professionals how it is done."

PHYSICAL THERAPY IN HOSPITALS IN NEW YORK STATE

The Special Committee on Physical Therapy has issued a summary of its report on a survey of the attitude of the hospitals of New York State toward physical therapy under the date of February first. This report may be compared with the report on "Physical Therapy in Ulster County" published on page 165 of the February first issue of this Journal. The summary of the State Survey is as follows:

Number of questionnaires sent out	250	
Number of replies received	173	70%

Question No. 1. Do you possess a physical therapy department?	*Yes*	*No*
Hospitals from all over the State.	57%	43%
Hospitals in metropolitan zone..	65%	35%
Hospitals outside of metropolitan zone	53%	47%
Question No. 2. Is it under the control of a qualified physician? ..	84%	16%
Question No. 3. Do you intend organizing such a department?..	34%	
Question No. 4. Can we be of assistance to you in this respect? —Number replying "Yes"	34	
Question No. 5. Would you want one of your physicians trained in order to be able to direct your physical therapy department?— Number replying "Yes"	11	

RICHARD KOVACS.
Chairman.

THE DAILY PRESS

OLD MAN WINTER

From the New York Herald Tribune, February 3, 1931. By J. N. Ding.

Old Man Winter has dealt kindly with New York State, especially the southeastern section in which the editorial office of the Journal is located. Whenever the Western Blizzard has threatened Eastern New York, the genial influence of the Atlantic Ocean and the Gulf Stream has tempered its rage and tamed its fury, so that the worst that is said about the weather is that it is changeable and so is unhealthful.

Any weather is "healthy" so long as humans prepare themselves for it. Mark Twain said that everybody grumbles about the weather, but no one does anything about it. The fact is that people expend more effort on the weather than on almost any other condition. Most comforts of modern civilization are the result of man's control of weather conditions. He heats his houses, arrays himself in clothing that is warm and waterproof, and travels warm and dry amid slush and mud. No matter what may be the outside weather, the man-made weather in his home, his office and his parlor car is that of a balmy day of May or September. Man's triumph over the weather is nearly complete.

There is little excuse for blaming the weather for sickness or epidemics. The greatest epidemic of modern civilization,—that of influenza in 1918,—occurred when unusually balmy weather prevailed. Man himself is the source of most human ills and infections.

THE STATE HEALTH COMMISSION

The recommendations of the New York State Health Commission which were abstracted on page 230 of the February fifteenth issue of this Journal, were the subject of editorial comment in the New York *Times* of February seventeenth. The point of view of the paper will be approved by physicians as the editor says:

"The investigation made by Dr. Farrand's commission somewhat resembles a survey on behalf of a successful concern with the object of turning out a larger and better product. The organization in charge of public health in the State of New York, in accordance with the proposals of the Biggs Commission seventeen years ago, has done well, but with certain changes it can do still better. Some of these changes cannot be brought about from within. They have to be provided for by the Legislature.

"Administrative methods can be made more efficient. Except in large cities, the local health unit should be the county, instead of the village or town, with full-time officers in charge of the executive work in place of part-time men continually changing. This plan is the outcome of recent experience in various States and is strongly endorsed by philanthropic foundations specializing in the health field.

"All the leading recommendations of the report are based on established precedent. Tested procedures exist for eradicating many diseases, and it is upon these that the program is founded. Elimination of diphtheria, typhoid fever and other infections offers little difficulty today except from the standpoint of administration. There is no question what should be done: the only point is how to carry the necessary measures into effect. The report recognizes that intelligent and active cooperation by the public must be secured."

HOSPITALS AND WORKMEN'S COMPENSATION

The *New York Times* of January 16 has the following editorial comment entitled "Fair Play for the Hospitals":

"Beekman Street Hospital is located in an industrial section of the city. That accounts for the fact, that, it handles more compensation cases than any other private institution. President Cullman thinks that they deserve the best of care, but that industry should assume the full cost of that care.

"There is no doubt that the intent of the workmen's compensation law, as originally written, was that industry should bear the full burden of the proper professional care and hospitalization of patients injured in industry," Mr. Cullman remarked at the annual meeting of his board. "At the present time Beekman Street Hospital receives slightly over 60 per cent of the actual cost of the hospitalization of patients coming under the workmen's compensation law.

"The difference between what it costs the institution and the amount received from the insurance companies is borne by the general public and by the trustees. It seems erroneous in principle that the patient be pauperized and that contributions be made for the benefit of insurance company stockholders.

"If the hospitals were more liberally remunerated for the care of these industrial cases, they could devote a larger part of their funds to needy patients outside the protection of the compensation law."

OLD-AGE INSURANCE

Governor Roosevelt, in his annual message, approved the Old-Age Security law, as was reported in this Journal of January, 15, page 109 The same Journal, page 113, quoted an editorial on the subject taken from the *New York Times*. Ex-President Coolidge comments on old-age pensions in his daily letter in the New York *Herald-Tribune* of January 26, as follows:

"Considerable investigation is being made of the problem of old-age pensions. Some governments and some industries have adopted such a system, and it appeals to our sympathies. Only the experimental state has been reached, so that its soundness has not been demonstrated. We are constantly trying to adopt reforms of some artificial nature so as to save ourselves from suffering from the defects of human nature as it is now constituted. No doubt some of our efforts are helpful, and the fact that we realize our deficiencies and are intent on remedying them is most encouraging. Our failures lie in attempting to reach the goal by some short cut without really removing the cause of the difficulty. We try to reform ourselves on the outside when the only effective remedy is reform on the inside.

"What a self-respecting people really needs is not a system of old-age pensions, but a population made sufficiently skilled by education and sufficiently self-controlled and well disposed by the help of religion so that old-age pensions would be a superfluity. Unless real reform comes from within, the problem will never be solved."

LOST: MIDDLE AGE

The life of a modern woman is divided into three parts—babyhood, girlhood, and old age—at least this seems to be the burden of the following editorial in the *New York Herald-Tribune* of January 28:

"The average normal middle-aged woman," says Miss Frances Perkins, State Commissioner of Labor, "has little use for the artificial creations of the stylists." Miss Perkins thinks that if the manufacturers of women's clothing would listen to the middle-aged women instead of heeding the flippant fancies of the flappers they could keep their employees at work twelve months in the year, and iron out seasonal unemployment.

"Strange doctrine this in 1931! Miss Perkins seems to have lost her usual salty realism. Where are the middle-aged ladies who create styles of their own? Time was when a woman was middle-aged when she crossed the fatal line of thirty years. Her skirts began to settle, indeed, before she passed twenty-five. Youth was short and distinctive. It is one of the crowning glories of our age that it has prolonged youth for Miss Perkins's sex and abolished the tedious interval of middle age. There still is such a thing as old age and we respect it. But middle age is gone. Miss Perkins, appealing to middle-aged women to look middle-aged and to insist upon middle-aged styles is like King Canute bidding the waves be still."

OUR NEIGHBORS

TREATING THE POOR IN NEBRASKA

The Law of the State of Nebraska goes farther than that of most other States in recognizing the right of a physician to compensation for treating the poor. The *Nebraska State Medical Journal* for February contains an excellent editorial quoting the law and decisions in regard to the pay of physicians for their care of the indigent. The following editorial is entitled "Poor Man Without Funds, Property, or Credit, Ward of County, Not of Doctor."

"As early as 1884 the courts of Nebraska were invoked to decide the rights of physicians and to state the obligations of counties with reference to the poor and indigent who may become ill or injured and require the services of a physician.

"Section 5153 of the Compiled Statutes provides 'that whenever any non-resident, or any other person not coming within the definition of a pauper, shall fall sick in any county of this state, not having money or property to pay his or her board, nursing, or medical aid, it shall be the duty of the overseers of the poor, of the precinct where such person shall be, to furnish such assistance to such poor person as they shall deem necessary, etc.,

"In the case of Gage County vs. Fulton (N. W. Reporter, Vol. 19, p. 781), decided in 1884, the supreme court said: 'It will be seen that the duty of maintaining paupers, and persons not coming within the definition of paupers, who shall fall sick in any county of this state, and not having any money or property to pay his or her board, nursing, and medical aid, devolves upon the counties; in other words, the statute makes the counties legally liable for the same.'

"More recent decisions of the supreme court in somewhat related cases are cumulative. (See Plumb vs. York County (N. W. Reporter, Vol. 46, p. 938); Shidler vs. York County (N. W. Reporter, Vol. 146, p. 949).) The case of Anderson vs. Pawnee County also bears out the earlier decisions. The most recent case bearing on and clarifying the rights of physicians and the duty of county authorities is that of Neslund vs. Dawson County, decided by the supreme court commission about two years ago and referred to in this *Journal* editorially, July, 1929, part of which we again quote:

" 'This does not mean that the board may arbitrarily avoid liability by a heartless disregard of the most obvious necessities of suffering humanity.

" 'The service of a surgeon or physician cannot be required as a matter of charity.

" 'In case of emergency the physician may hold the district liable although he acted without the request or consent of the person designated as overseer of the poor.

" 'In a proper case the physician may hold the district liable even in the face of the refusal of consent, if lawfully or arbitrarily withheld.

" 'Neither the county commissioners nor the town supervisors can turn their backs upon the proper claims of a poor person.

" 'Nor can it be said that the unfortunate pauper, who has met with an accident requiring instant succor is to be remediless; the county or town must provide for him as soon as they may.'

"The Neslund vs. Dawson County case, it seems, hinged largely on the definition of the term 'indigent.' It was shown that the father of the injured boy was working at the time of the accident, but was without ready money and was without credit in town. Webster defines 'Indigent: Destitute of property or means of comfortable subsistence.'

"All this points clearly to the proposition that the county is liable not only for paupers, but for emergencies occurring to indigent persons within their jurisdiction.

"Medical men have had much difficulty with county authorities taking the proper viewpoint and it is possible that lack of diplomacy in presenting the cases was at the bottom of at least some of them. The above references indicate that the courts have passed upon the question a sufficient number of times to clarify the matter and nothing but absolute stubbornness on the part of the board can account for refusal to accept obligation in these cases.

"A recent case settled by the county board may be of interest in this connection: A married man, father of four children, a fifth child expected, ranch laborer at prevailing wages, suffered a violent attack of appendicitis. The physician consulted diagnosing imminent rupture, at once took the patient to a hospital and he was operated upon without delay. The patient had stated that he was without money and that he usually drew advances on his wage account. The physician, immediately after the operation, notified the county commissioners of the case and facts pertinent thereto, and stated that under the circumstances the county board would be asked to assume the financial obligation. In due time bills were rendered by the hospital and by the physician and surgeons and the supreme court decision in the

A DUAL ATTACK

N THE treatment of rheumatism outanding authorities emphasize the alue of associating salicylate mediation with alkalis. By means of this ombined attack the acid toxins of ie bacteria of rheumatism are neuralized, and at the same time it ecomes possible to bring about a essening of the cardiac dilation ssociated with rheumatic disorders.

'o insure safe and effective alkalizaion, the Wm. S. Merrell Company – pioneers in salicylate medication – have combined Merrell's Natural alicylate with a *balanced alkali* in ne formula—

ALYCIN

Alycin enables the physician to push he dosage of salicylates at the outset of treatment, without the danger of setting up untoward side-effects.

Alycin is indicated in the treatment of rheumatism, arthritis, colds, influenza, the neuralgias, and all conditions wherein the salicylates are used.

We invite you to write for a trial package of Alycin and full literature so that you can submit the product to a test.

Neslund vs. Dawson County case was cited for authority. Later the board asked the physician to appear before them and in a quiet, dignified manner the matter was fully explained and the decision of the supreme court read, whereupon the county attorney, being asked for his opinion, stated that, assuming that the emergency claimed, existed, the county was liable. The bills were allowed.

"The facts above given and citations made should make it easy for physicians throughout the state to show to the county authorities the law and decisions appertaining thereto, and to convince them of the rights and duties of the respective parties in cases coming under Section 5153, Compiled Statutes relating to paupers and indigents."

ADVERTISING BY COUNTY SOCIETIES IN WISCONSIN

The proposition is frequently made that County Medical Societies advertise in the daily newspapers, emphasizing the slogan "Pay Your Doctor" and calling attention to the services rendered by family physicians. The idea is opposed in an editorial in the *Wisconsin Medical Journal,* which says:

"From time to time there comes to the profession proposals that group advertising will solve the economic ills to which the medical profession seems to be heir. On this general subject we presented our conclusions editorially, April, 1930, declaring our belief that advertising would solve none of our problems and would ill serve the public.

"More recently, however, it was proposed to members of the Dane County Medical Society that they finance a program of insertion of twenty-six, full-page, syndicated advertisements which had as its desideratum educating the public to a greater appreciation of the services of the profession with the thought that they should pay their doctor 'first.' Wisely, we believe, the Dane County Society voted unanimously, after a full and frank discussion, not to approve such an advertising campaign.

"The physician maintains no credit bureau upon which he decides whether the patient is a good 'risk' as an installment purchaser of health. So long as he is a good physician, be he in country or city, his first concern is with his adversary—death. Being human, the physician wants to get ahead financially. We know of no great physician (and there are many, many such in our State today) who has made money his only standard of values.

"At this particular time of economic stress among the laboring classes, when the profession

of Wisconsin should be the first to extend charity by free treatment or extension of time for payment and is so doing,—we would bring proper condemnation upon ourselves by asking our patients to please pay us first,—cash in advance preferable. Even if we were concerned only with cash in our pockets, this particular scheme would serve us ill.

"We will never be more perfect than other human beings. We have our commendable points. We have our lamentable failings. As an organization our State Society is properly primarily interested in securing the highest type of service for the people of the State. It is properly interested in securing for the physician such financial position as is eminently just and as will attract to a great profession those who have the greatest capabilities. And we believe that the officers of the Society are far-sighted when they say that in perfections of our services lies our proper pecuniary reward."

WOMAN'S AUXILIARY IN THE EASTERN STATES

The February issue of the *Kentucky Medical Journal* has an outline of what the Eastern States are doing in the Woman's Auxiliary, and says:

"New Hampshire stands alone as the only New England state 100 per cent organized and cooperating with the National Organization. Last year the State Auxiliary had misgivings as to its necessity and usefulness but an urgent request from the medical society that the women remain organized, dispelled all doubts.

"The New Jersey Auxiliary made pilgrimages to state institutions, set apart one meeting when the mothers of physicians were entertained, and sponsored various health meetings. The Essex County Auxiliary, assisted by the physicians, succeeded in establishing a course of health talks, in cooperation with the Y.W.C.A. of Newark, emphasizing especially pre-natal care and information which would aid the mothers of babies and young children.

"Virginia is active in spots. The doctors encourage the auxiliaries as they believe that through them education with regard to the menace of state medicine can be spread.

"Ohio for several years has been sending representatives from a few organized counties to the national meetings but as yet there is no state organization. As our friend and adviser, Dr. Upham, lives in Ohio, it is felt that he will advise the National Auxiliary when the auspicious time arrives for the establishment of a State Auxiliary.

This Bottle went with Byrd to the Antarctic

THIS much traveled bottle could tell an exciting and romantic story. Its contents originated in the selected livers of fine cod-fish, harvested in the Lofoten Island Waters of Norway, far within the Arctic Circle. Extracted and refined in the Nason Plants in that romantic land of the Midnight Sun, biologically tested and bottled at the Tailby-Nason Laboratories in Boston, a quantity of this potent, palatable Cod Liver Oil went with the Byrd Antarctic Expedition to the South Polar Regions.

The bottle illustrated was brought back and given by Admiral Byrd to the Tailby-Nason Company as a souvenir of the Expedition, its contents unaffected by the long sojourn in the icy wastes of "Little America."

(*Continued from page 310—adv. xvii*)

"The District of Columbia seems so completely diverted with Washington affairs that the Auxiliary which so capably cared for the A. M. A. meetings some years back seems to have gone into retirement.

"Delaware in a breathless, better-late-than-never manner, has completely caught up and is most interested and active and has entered upon serious work by assisting the men of the profession in establishing a medical library in Wilmington. They will cooperate with Philadelphia at the time of A. M. A. and the eastern section will introduce them with pride to the National Organization.

"West Virginia is up and doing and you may expect still better things from that state this year.

"Maine, Massachusetts, Rhode Island, Vermont and Maryland have reported the interest of individuals but no organized effort. Queries from different localities in New York as to why there is no auxiliary have been answered with the statement that several years ago the House of Delegates voted unanimously in favor of the auxiliary and authorized its organization. The same year Connecticut voted favorably but no definite steps have been taken.

"Pennsylvania has surely discovered the rhythm in which its auxiliary work is best done, for concrete accomplishments have been turned out regularly, year by year. Of the three thousand dollars contributed last year to the Medical Benevolence Fund more than two-thirds was contributed by the Auxiliary. A definite trend toward educational meetings is felt all over the state and socially it is hoped that the carefully formed Philadelphia plans for the next meeting will bring honor and glory to the Keystone State. Not only are the adult members of the Auxiliary meeting but a group of the most charming and good-looking daughters of doctors are working together in order that they may know each other and work in unison for the comfort and pleasure of the A. M. A. guests when they come to Philadelphia in May. Verily, who can question the wisdom of the Auxiliary, when it brings about so much willing work in behalf of the medical men of the country?"

FINANCES OF THE COLORADO STATE SOCIETY

The following table from the December number of *Colorado Medicine* describes the finances of the State Society, as set forth in the annual report of the Committee on Appropriations:

"Your Committee on Appropriations begs leave

UNETHICAL PRATICE IN IOWA

The January issue of the Journal of the Iowa State Medical Society has an editorial unfolding in almost incredible chain of unethical medical practice. Concerning a physician, B., the proprietor of a healing institute, the editorial says:

"Many readers of the Journal have more than passing interest in the activities of Norman Baker, of Muscatine, notorious for his vitriolic

(*Continued from page 313—adv. xvii*)

attacks upon the medical profession, the American Medical Association, his former partner one Harry Hoxsey, *The Muscatine Journal* and, in fact, anything or anybody who opposes him. His activities have carried him into many fields and given him widely diversified interests. He first received public notice when by means of Radio Station KTNT he advised the world that he had solved the mystery of cancer and invited patients to his institute for treatment. Modest, at first, in his claims he soon expanded until his advertising declared cures for goiter, varicose veins, and other maladies besides cancer.

"Harry Hoxsey, erstwhile of Illinois, was discovered by Baker, who invited him to join the personnel of the institute. Money rolled into the coffers of the institute, according to the testimony of Hoxsey, and then trouble began. The Attorney General's office began court action to restrain the five officers of the Baker Institute from the practice of medicine without license. On third trial an injunction was secured restraining the four associates of Baker from the practice of medicine but Baker himself escaped injunction. About this time Hoxsey left the employ of Baker and started his own cancer clinic in Muscatine in opposition to Baker. He further entered several suits against Baker for slander ($250,000) and for money due him under contract ($85,000). These suits are pending. The injunction instigated by the Attorney General has been appealed to the Supreme Court. The Federal Radio Commission having received voluminous complaints against his alleged misuse of his Radio Station KTNT suspended his license, but has extended his probation from time to time pending final disposition of the matter. This brings his story up to about the first of December.

"During the month of December we note that Baker has sought to secure approval of articles of incorporation for the Baker Institute from the Secretary of State. He has petitioned the radio commission for an extension of his temporary license to operate his radio station until January 31, 1931. This petition has been granted. Criminal action has been started by County Attorney Harold E. Wilson of Muscatine against Bruce Miller, formerly a member of the Baker Staff, for practicing medicine without a license. A civil suit was also filed in which the State seeks enjoin him from practicing medicine in Iowa. Most spectacular of his recent activities is the invitation which Baker extended to President

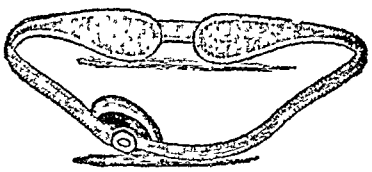
VENTRICULIN (Desiccated, Defatted Hog Stomach)
SPECIFIC IN PERNICIOUS ANEMIA

Accepted for N. N. R. by the Council on Pharmacy and Chemistry of the A. M. A.



The remarkable potency of Ventriculin—a dry, granular palatable extract from fresh stomach tissue—has quickly made it an outstanding preparation for the treatment of primary anemia. . . . Its efficacy is assured by clinical trial, each lot being clinically tested and approved by the Simpson Memorial Institute for Medical Research of the University of Michigan. The material must be shown to contain the requisite degree of blood-regenerating activity before being released for general use. . . . The usual dose of Ventriculin is 10 grams daily for each 1 million reduction of the red blood cells below normal; maintenance dose, 1 vial daily. . . . You will be interested in the new booklet "*Ventriculin in the Treatment of Pernicious Anemia.*" It will be sent you promptly.

Hoover to assist in the ceremony opening his new print shop which is now printing a daily paper under Baker's control. Judging from the editorial comment reaching our attention the Iowa Press feels that President Hoover's participation in this ceremony was untimely and ill-advised."

All this reminds one of the Brinkley case in Kansas, which was outlined in this Journal of December 1, 1930, page 1425.

CONVICTIONS FOR ILLEGAL PRACTICE IN NEW JERSEY

The January issue of the Journal of the Medical Society of the State of New Jersey contains a communication from Dr. J. J. McGuire, Secretary of the State Board of Medical Examiners, outlining the convictions of twenty-one persons practicing medicine illegally. These convictions were secured between September 8, 1930, and November 5. Five of those convicted were women, judging by their names, some of which were those of foreigners.

The classification of the defendants was as follows:

Plain practice of medicine	9
Physiotherapists	5
Druggists (one also a naturopath)	4
Naturopath	2
Psychoanalyst	1

This seems to be an excellent record for the New Jersey Board.

CHRISTIAN SCIENCE IN OHIO

The Christian Scientists of Ohio are planning to introduce a bill in the Legislature legalizing their practice of healing by prayer.

The *Ohio State Medical Journal* of January says:

"An unusually active and vigorous campaign has been waged in Ohio for many months by leaders of the Christian Science Church in an attempt to win support for the proposal which it expects to sponsor in the forthcoming session of the Legislature. This measure, it is understood, would supplement Section 1286 of the General Code with a section providing that the provisions of the act 'shall not affect nor interfere with the practice of the religious tenets of any church, provided that all sanitary laws and regulations of the state are complied with.'

"The fallacies of such a provision are many. They should be quite obvious to the members

(*Continued on page 317—adv. xxi*)

(*Continued from page 316—adv. xx*)

lhe Legislature upon whom the entire re nsibility in this matter rests.

If the only legal restriction placed on faith lers should be compliance with the sanitary s and regulation of the state, it would be t as consistent to permit attorneys, school chers, carpenters, plumbers, or whatnot, to it the sick (practice medicine) if they com- with the sanitary laws and regulations

Legislators may be reminded that a re- ous prayer is one thing; a commercialized yer quite another, especially when the er is offered as a complete substitute for science of medicine in the prevention and atment of disease."

GRIEVANCE COMMITTEE IN WISCONSIN

The *Wisconsin Medical Journal* for February the following note regarding the plan to form Grievance Committee in Wisconsin somewhat ilar to that in New York:

'In accordance with recommendation of the uncil of the State Medical Society of Wiscon- at its January meeting, Senator Walter Hunt River Falls has introduced bill number 58 S ablishing a state grievance committee.

'Under terms of the bill suggested by the State ciety, the committee will be composed of the torney General, or the Deputy Attorney Gen- l, the Secretary of the State Board of Medical aminers and the Secretary of the State Board Health. The Secretary of the State Board Health will act as chairman of the committee. ie committee will have the power to issue sub- enas and to investigate such practices as are mical to the public health.

"The medical grievance committee plan was st established in New York State and the Wis- nsin committee is modeled, in its thought, after e New York law. The senate committee on lucation and public welfare had a hearing on is plan on Tuesday, February 3rd."

COUNCIL OF THE WISCONSIN STATE SOCIETY

The Council of the State Medical Society of Visconsin met on January 3, and received re- orts which are full of information and interest. he minutes of the meeting are printed in the ebruary issue of the *Wisconsin State Journal*.

Medical extension is supported by an appropri- ion of $7,500 annually made by the State Leg- lature. The Journal says:

"The Joint Committee has recommended that e Legislature be asked to increase the budget

RELIEF in HYPERTENSION

PROMPT and safe reduction of blood pressure, pending determination and treatment of the cause, has been effected in thousands of cases by the use of Pulvoids Natrico.

Pulvoids Natrico differs from the drugs classed as vasodilators in that it not only lowers blood pressure but keeps it down safely and surely.

Pulvoids Natrico is a synergistic combination of approved vasodilators (sodium nitrite, potassium nitrate and nitroglycerin) in combination with Crataegus Oxyacantha.

A physician writes: "Pulvoids Natrico seems to be ideal in all hypertension conditions. Has given me, and all patients to whom prescribed, genuine satisfaction and I do not believe there is another preparation, single or combined, which can in any wise approach its efficacy or efficiency. It is a meritorious remedy, and I can recommend it conscientiously to all my colleagues."

It is significant that physicians that have used Pulvoids Natrico in cases of hypertension invariably continue to place their dependence on it. Try Pulvoids Natrico for yourself and check its results on the sphygmomanometer.

for Medical Extension by $4,500 a year to make the total $10,000 a year. The Committee has in mind the employment of a full-time director of activities at $3,000 and $1,500 additional for the free lecture services. While it was thought that securing any additional allowance was highly improbable, it has just been passed by the Budget Committee of the Regents and, after something of a fight, by the Regents as a whole. It now goes to the Legislature with the approval of the University regents. This would mean, if the grant is approved, that, beginning July 1st, next, there will be spent in Wisconsin $13,000 a year from State funds for the furthering of medical extension in this State. No other State has anything approaching this budget."

The State Society conducts a medical service, which is described as follows:

"This service, instituted upon request of the Secretary, is today possibly the Society's greatest scientific accomplishment. In addition to the financial grant from the Extension Division, an additional $3,000 is given by the Medical School. With this total from $5,500 to $6,500 the Library offers four services:

"(1) The loan of recent literature on any given subject by packets made up from a subscription list of over 300 leading medical journals. Cost to the physician is postage and wrapping both ways.

"(2) Loan for limited period of given journal or journals each month. Cost to physician is ten cents a month.

"(3) Compilation of bibliographies or list of references on a given subject. Cost to physician is 60 cents an hour; but inasmuch as such lists are now in readiness for all leading subjects, present cost is only for the time needed to bring the list to date.

"(4) Loan of books from the Extension Library, the Medical School Library, or securing them from one of the national institutions. Cost is postage and wrapping both ways."

District meetings are described as follows:

"3. The District Meetings. A few years ago but few districts had an annual district meeting. The Ninth District where Dr. Jos. F. Smith has long had four excellent meetings each year was a notable exception. For the past three years each district has had an excellent meeting and they now appear to be firmly established as a means of securing program material of a calibre that the average county society would be unable to have."

The financial report of the Journal for the year 1930 is as follows:

HOSPITAL ADVERTISING IN WEST VIRGINIA

The question of advertising hospitals through the channels of ordinary publicity is discussed in the January issue of the *West Virginia Medical Journal* as follows.

"The question of hospital advertising comes up from time to time. Just now there are two agencies in West Virginia that are endeavoring to secure advertising matter from hospitals. One is telephone directory advertising and the other is bus advertising. We do not know of any hospitals that have signed up for either of the above-mentioned forms, but we do know that various West Virginia hospitals have been solicited on this matter

"The question might easily be raised as to whether or not bus or directory advertising would be strictly ethical. If so, to what limit could a hospital go? If not, is there any other form of ethical hospital advertising? It seems to the Journal that this is a matter for the Hospital Association of West Virginia to thresh out. Dr. B. I. Golden, of Elkins, president of the Hospital Association, has suggested that all prospective hospital advertising campaigns be submitted to the Hospital Association for approval before any campaign is undertaken. The idea is to be commended If properly carried out, it could be the means of promoting a better spirit of undertaking and cooperation between the hospitals of this State."

SPEAKERS' BUREAU IN IOWA

The Iowa State Medical Society has a Speakers' Bureau which supplies lecturers for County Societies and lay health organizations The January issue of its Journal announces that the programs are available in the following subjects

Contract practice
Medical Economics
What cults have taught the members of the regular profession
Medical insurance, the points of view of (a) the agent (b) the medical examiner, and (c) the practitioner.
Thyroid
Peptic Ulcer.

In December lecturers were sent to five county societies, one dental society, and two fraternal clubs.

The February number of the Journal has the following account of the offer of the Speakers' Bureau of the State Society to make up the programs of county societies

"The energy of the Speakers' Bureau has been directed in still another direction Through co-

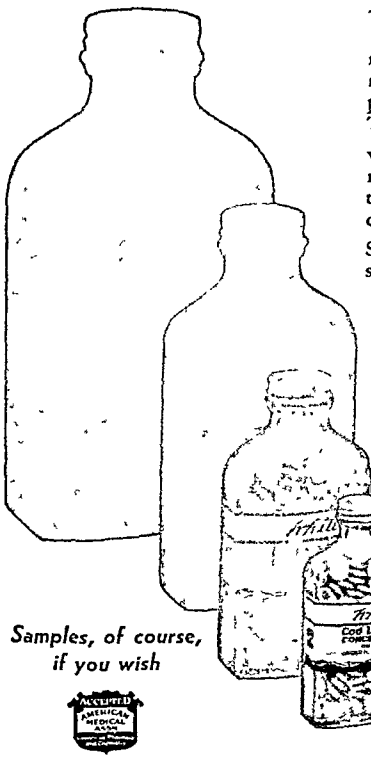
operation with the Iowa Tuberculosis Association, the Bureau is now in a position to schedule chest clinics as one of the regular program services offered to county medical societies. The Tuberculosis Association has consistently urged that these clinics be conducted as a regular county medical society program, and in taking over the task of making a clinic schedule, the Speakers' Bureau wishes to emphasize this point. The preferred procedure is to hold the clinic from 1 to 5 p. m. followed by 6 o'clock dinner and a scientific program on diseases of the heart and lungs. The Bureau will be very glad to plan the evening program.

"These clinics are given upon the invitation of the president or the secretary of the county society. After the date is definitely fixed, the preliminary arrangements for the clinic are made by a public health nurse, sent from the staff of the Iowa Tuberculosis Association a few days prior to the clinic. The clinic is held primarily for the benefit of the physicians, and should not be regarded as the usual diagnostic clinic, but as a demonstration of newer methods of examination and treatment. The patients are selected and referred by members of the county medical society. In order that the greatest benefits may be secured, physicians from adjoining counties should be invited to attend the entire day's program.



"The value of these clinics has become well known to the medical profession throughout the state. The schedule is rapidly becoming filled and further requests should be made as soon as possible. Plans are so made that Friday is the most convenient day to hold these clinics, but in the event that the county medical society meeting date cannot be changed adjustments can usually be made."

MEDICAL PUBLICITY IN KANSAS

The physicians of Kansas like those of several other states are seriously considering publicity methods directed to the people. The Journal of the *Kansas Medical Society* for February has the following record:

"Following the adjournment of the Council a meeting of the Board of the Bureau of Public Relations was held. There was considerable discussion concerning methods for giving greater publicity to scientific medicine. Several unsatisfactory features of newspaper advertising were mentioned. The results in some instances have not been all that was expected. A proposal by the executive secretary of the Bureau to publish a popular health magazine in connection with the Journal received some consideration but it was finally decided to leave the matter for final action at the annual meeting."

In Pregnancy and After

WHEN you have to provide for the increased metabolic requirements of the gravida—for her calcium needs—if she needs building up and protection (particularly if there are TBC contacts), *or* . . .

when you wish to afford her the added resistance to infection (particularly of the intestinal and respiratory tracts) conferred by Vitamin A—

She will keep on taking your prescription gladly and regularly, if it is

PSYCHIATRIC OBSERVATION CLINIC IN DELAWARE

The State of Delaware has the excellent plan of holding its psychiatric cases under observation for some time before committing them to a hospital for the insane. The January issue of the *Delaware State Medical Journal* comments editorially on the plan, as follows:—

"The Psychiatric Observation Clinic of the State of Delaware will be opened by the first of February. Other states have observation clinics in which patients who are suffering from mental and nervous diseases are studied and diagnosed before being committed to a state hospital, but Delaware is one of the few states which has a period of observation for all before they are regularly committed. It is fortunate that our state is small in area as well as in population, for only in such a situation can so comprehensive a plan be carried out. It is possible to produce an ideal situation under such favorable circumstances.

"A clinic which studies all types of mental and nervous diseases as well as those actually psychotic before commitment is a valued addition to any state institution. In many instances actual residence in a hospital for mental diseases may be avoided. This would be particularly true of patients suffering from certain types of toxic psychoses, mild depression, etc. The institution to be opened has facilities for forty patients —twenty male and twenty female. It is a complete hospital unit in itself, being fully equipped for all types of diagnoses and treatment. Among other factors there will be a portable x-ray unit, an individual dental unit, physio-and hydro-therapy, etc."

CELLU

Bran Wafers

are adaptable to your Diabetic and Ketogenic Diets

A Supplement to Bread
Cellu Bran Wafers are made chiefly of Cellu flour and washed bran, skillfully blended to make a cracker "wheat like" in flavor. Served with butter are a good substitute for bread.

Non-Nutritive
Cellu Bran Wafers are composed of such ingredients that the resulting wafer is practically without food value. This composition makes their use as a "filler", to increase the volume of the diet, very desirable.

Increase Bulk
Cellu Bran Wafers being composed almost entirely of Cellulose are a good source of indigestible residue in the diet.

Vol 31, No 6 NEW YORK, N Y March 15, 1931

THE ECONOMIC CONTRIBUTION OF PHYSICIANS TO THE COMMUNITY

By CHARLES GORDON HEYD M D, NEW YORK, N Y

An Abstract of the inaugural address of the President of the Medical Society of the County of New York delivered on January 26 1931

THE Medical Society of the County of New York is dedicated to the propositions that

I The fundamental object of medical practice is to provide and make available adequate, effective and efficient medical service at all times for every member of the community regardless of race, color or creed

II Medical service as provided today is in a large measure effective and efficient although not always adequate or available

III The payment to physicians for medical service is not a large item in the so called cost of medical care, as only about fifty per cent of patients hospitalized in general hospitals pay a doctor's fee

IV There is no logical reason for believing that the professional item for adequate and effective medical service in the cost of medical care can be materially lessened or reduced On the contrary, there are many reasons for believing that it will be increased as it must eventually have added to it a charge for professional services

V The doctor is a citizen and must discharge all of his obligations of citizenship the same as any other member of the community

VI The doctor is entitled to a monetary return for his labor that is fair and commensurate with his services, training and experience The fact that the practice of medicine is a profession does not mean that the doctor shall continue to work under a system that is ethically wrong and economically unsound The doctor must be paid for his services in order to function as a useful and contributing member of society

These postulates present the background for my remarks and serve as an introduction as to what is the economic contribution of physicians to the community

Physicians Annually Contribute to the Community 365 *Millions of Dollars in Free Medical Service* It is claimed by competent statisticians that physicians treat one eighth of the population of the United States free of charge Since at all times there are two per cent of the population incapacitated and about four per cent physically impaired, it follows that from 375 000 to 500,000 persons are daily treated without charge If only $2 00 per person were charged for a treatment, the sum total monetary equivalent for the contributions annually made by physicians in the form of free medical treatments would be $365 000,000

Physicians Largest Contributors to Medical Charity If all the medical and quasi-medical foundations were consolidated into one organization their entire contribution to society in dollars during the last twenty years is not equal to the annual donation of the physicians of the country The medical profession may, therefore, justly claim that under the present medico social system they stand without a rival in the entire field of medical charity and health philanthropy

Average Physician's Annual Income $3,000 This immense philanthropic enterprise is created by the labors and services of 150,000 physicians working for an average remuneration of $3,000 per annum

The Costs of Training a Physician $28,000 The doctor today is about twenty eight years of age before he begins practice What has it cost in actual dollars to produce this educated and trained product His pre-medical and medical education will certainly cost, with fees, maintenance and miscellaneous expenses, $16,000 His loss of earning capacity while being professionally educated may be estimated roughly for six years as $12,000

This young man then begins practice at twenty-eight years of age, with an estimated indebtedness of $28,000 upon which he should pay $1,400 a year as interest I seriously doubt, although I have no figures to verify it, whether eighty per cent of the doctors ever overcome this primary indebtedness of $28,000 In other words, more than four-fifths of our profession never repay

their capital investment by leaving an estate equal to $28,000 and never make up the carrying charges by annual savings of approximately $1,400. To just break even the doctor must logically pay interest of $1,400 per year and create a capital of $28,000 before he dies.

Middle Class Receiving Competent Medical Care: That the medical service provided by doctors in the last thirty years has on the whole been effective is indicated by a study of the mortality rate in 1900 as compared to the mortality rate in 1925. If the medical service given to the middle class (white collar) were ineffective or inadequate, then we should expect to find that as a class they suffered from such defects of medical service. This is not apparent because the decline in modern mortality is impressive.

Mr. Wolman has calculated that based on the death rate obtaining at the beginning of the century, in 1925 there would have died 1,962,999 persons, but actual deaths were only 1,389,673 persons, a saving of 573,326 lives.

In this connection it is interesting to note that only something over four million Americans submit any income tax reports at all, and in 1927, 1,600,000 of these paid no taxes because exemptions exceeded net income. As returns are expected when income reaches $2,500 for a married person, or $1,500 for a single person, these figures throw a powerful searchlight upon the phenomenon of our ability to pay for things.

Assuming twenty-seven million heads of families, less than ten per cent had income sufficient to warrant the preparation of a tax return with the expectation of making payment.

It follows that with only 43 per cent of the community gainfully employed and 87 per cent of the community receiving less than $2,000 a year, no matter how much the cost of medical service can be reduced, it cannot be reduced sufficiently low to allow this large group of the community to pay for their medical services within their income.

More Spent on Non-Essentials Than on Medical Care: On the other hand, a superficial survey of the aspects of some of our social activities will indicate the tremendous amount of money that is paid out for non-essential luxuries. The outlay for cosmetics, cigarettes, chewing gum, are expenditures that are in no sense necessities and are distinctly in the luxury class. These luxury expenditures total over five and a half times the total cost of all non-government health services. The amount spent for tobacco alone is three times as much as that spent for physicians and the American people spend more for candy than they do for doctors.

Public Makes No Provision for "Upkeep Costs" of Human Machine: One of the fundamental difficulties in the consideration of the high cost of illness is that the public have not been educated to realize that a certain sum of money must be expended to keep the human machine in a state of efficiency.

There are approximately 450,000 persons passing through the wards of the New York hospitals in a year; practically 1,500,000 other citizens avail themselves of the dispensaries. It is evident that this entire group of people, nearly 2,000,000, make no provision for paying a physician or for periodic visits to their doctor.

Deferred Payment Plan in Purchase of Health Care: A very important aspect of the problem is that when sickness appears the cost and expenditure under the present system of payment is an immediate one, forced and made under stress.

Out of every 100 who borrow from small loan companies, an average of 28 persons do so because of expenditures arising from illness or death. Interest rates on these loans vary from 12 to 42 per cent per annum, which materially increases the burden of the average wage earner with a family.

There is hardly a member of the community who is gainfully employed that would not be able to handle a reasonable professional charge, in keeping with his economic position, if the load or charge were spread over a sufficient period of time. It seems inevitable that we must come to some scheme whereby the cost of the professional attention, or even the hospital, might be spread over a sufficient number of months to enable the patient to liquidate his indebtedness and be a self-respecting, responsible member of the community.

Free Medical Service for Those Who Can Pay Against Public Interest: It is not for the best interests of society that such a large body of the population should be remiss in their rightful obligation and obtain their medical services free of charge. It is not good public policy to disburse money given or donated, or extracted from the public by taxation, for such widespread free hospital and medical services.

Undue Economic Duress on Medical Profession Liable to Lower Quality of Medical Service: There are other economic disabilities that are enforced on the doctor as against the other professions.

From tribal times of medical priestcraft, through various ages up to our present order the medical man has been expected to present to the community the services of his time and mind without remuneration. Clinics had their birth and flourished, hospitals grew from small beginnings to extensive centers, and brick by brick in the construction of these units there has always been free medical work by innumerable members of our profession.

Any system that concerns itself with medical care must bear in mind that the fundamental conception is the quality of medical care and not the

scheme of organization or its financial background

Any plan, whether devised by doctors themselves or imposed upon the medical profession from outside sources, that diminishes the incentives for competent medical attention upon the part of the physician in the care of his patient or that takes away from him the rewards that accrue to superior ability, energy and conscientious discharge of his duty, must in the long run prove detrimental to society (Rappleye)

The Relation of Physicians to Clinics It is a fact that I think can be fairly well substantiated that eighty per cent of the practice of medicine requires no great or elaborate study, that the conditions for which people commonly seek relief are functional and not organic, that these complaints can be comprehended under the loose designations of headache, insomnia, colds, sinus trouble, tonsillitis, constipation and other more or less functional disturbances

The primary function of the clinic is to provide the means of correct diagnosis and treatment for sick people

No matter how you argue the question, nor how much money may be behind the idea, without the doctor there is no clinic and no medical charity I often wonder just how much the donor of a large sum of money to a clinic personally knows as to how much medical service his dollar buys, is the donor having his dollar expended to produce the greatest amount of effective and efficient medical service or is the large percentage of his dollar going into the secondary functions of administration?

It seems to me that the present clinic practice is failing through defects of its own creation and that the present clinic system cannot go on and function on a charity basis either for the patient or the physician The best social asset in the solution of this problem is the conservation of the physician class and the utilization of the family doctor

The establishment of a free clinic by a philanthropist without the employment of paid physicians is a most unphilanthropic act Such an individual is forcing other sick people who are already burdened with debts and whose incomes have stopped, to hire and pay doctors who attend the patients in the free clinic No free clinic should be permitted to operate without reimbursing the attending physicians for their time

It would be a splendid move in social medical adjustment (1) to curtail the unrestricted system of gratuitous relief, by excluding those not entitled to gratuitous medical advice, (2) to insist on the payment of the medical staff engaged both in in- and out-patient work, and the payment of fees by patients in the pay ward and in the consultation departments of voluntary hospitals

If the doctor could be assured of, let us say, a minimal revenue from all the patients that he takes care of he could well afford to permit a reduction on some percentage of his work But what is attempted if one may judge from recent newspaper publications, is to oblige the doctor to continue his free medical service and at the same time accept a reduction in his charges to the patients that he takes care of and who are occupying certain types of rooms which are essentially private hospital accommodations

Medical Publicity At the outset of any discussion concerning the appearance of a doctor's name in the newspapers, with or without his photograph, it is well to distinguish the two forms in which health information is promulgated, one is publicity and the other advertising

Medical publicity has for its object the informing of the public as to what is desirable for the maintenance of health, and concerns itself with the broad objects of preventive medicine and as a means of elevating the general standard of personal and community hygiene, sanitation and health The efficacy of any program of medical publicity must be appraised under the following headings (1) it must be news, readable and interesting, (2) it must be constructive and worth while for the social welfare of the community, (3) it must be in good taste, and (4), most important of all, it must be scientifically and medically correct

There is a field wherein organized medicine and duly qualified physicians should give out or promulgate publicity for health purposes, publicity for preventive medicine, publicity for civic problems that contact with organized medicine but no member of this Society should use the broad conception of publicity for health purposes as a means of personal aggrandizement or for inviting attention to himself, or for advertising a particular proprietary preparation When a member of this Society recommends soap to keep the body clean he may be engaging in worthy publicity and spreading abroad useful health information When however, the same member recommends the soap of Mr X he is not engaging in helpful health propaganda or publicity, but is becoming an active agent in the advertising of a commercial product, manufactured by a particular firm and it is just at this point that we differ with the said member

The prohibition of advertising placed no physician at a disadvantage Medical groups—hospitals and clinics, and departments of public welfare should be bound by the same rule of ethics as individual physicians A hospital is not operated to make money and therefore should not advertise in lay magazines or newspapers

Your President recommends to the Medical Society of the County of New York

(1) Provision that any member of the Society associated or identified with any organization

medical or lay, resorting to direct advertising for business be dropped from membership.

(2) A provision that any member of a County Medical Society giving an address over the radio on medical subjects shall submit the subject matter in typewriting to the Committee on Publicity of the Medical Society of that County for editing and approval, at least two weeks prior to the giving of the address. The information must also include the purpose for which the address is being given, remuneration if any, and the objective sought.

(3) A provision that when industrial corporations desire a medical speaker the request shall be considered individually and on its merits and no member of the Society shall give a radio address under commercial auspices without the approval of the Committee on Publicity.

(4) A provision that the publication of a photograph and signature of a member of the Society endorsing either directly or by implication a commercial proprietary or advertised article, shall be deemed sufficient evidence to warrant expulsion from the Society.

(5) A provision that if a member of the Society is the author of a paper or subject of public interest and desires to have a copy or abstract released to the lay press simultaneously or after presentation the request must come with copies of the paper to the Publicity Committee before permission can be granted.

(6) A resolution to the effect that members of the Society should be warned that the giving of interviews to the lay press is often associated with undesirable results which may subject the member to a citation before the Censors. Furthermore, if any member considers such an interview desirable the press representative should be referred to the Medical Information Bureau.

Is Medical Ethics "Bunk"?: From time to time we hear a great deal derogatory to medical ethics and within recent times the code of medical ethics has been declared "bunk." Fate, political chance and accident elevate men of varying ability to high places whereby they speak with authority, but it does not always follow that the mere elevation of a particular man to a place of political prominence at the same time raises his intelligence or increases his capacity for clear thinking. History records innumerable instances where an individual has abrogated to himself all knowledge and set up a personal opinion as divine wisdom.

What is the so-called "Code of Ethics" that has been anathematized as "bunk," "archaic," etc.? On May 21, 1923, less than eight years ago, the Medical Society of the State of New York by its House of Delegates approved of a set of resolutions called "Principles of Professional Conduct of the Medical Society of the State of New York." These were prepared by a committee under the chairmanship of Dr. E. Eliot Harris and composed of Dr. Samuel A. Brown, Dr. Walter L. Niles, Dr. William Darrach, Dr. George David Stewart, Dr. Grant C. Madill and Dr. Henry Lyle Winter.

The Principles of Professional Conduct are binding upon the component societies of the Medical Society of the State of New York. They were designed primarily for the benefit of the community. They define the duties of a physician to his patients and their fundamental purpose is to protect the patient and to assure to him correct treatment, right conduct and personal responsibility upon the part of the physician. In their broad scope they define the relation of a physician to another physician, and demand of every member of the Society a high standard of honor, personal integrity and conduct of a gentleman.

The Code of Ethics is a simple collection of precepts for good conduct. It appeals to all physicians for honorable dealing, for goodwill, courtesy and instinctive honor. It is not archaic, and there is not a single statement in that Code of Ethics that is contrary to our conception of right conduct and good citizenship.

The Medical Society of the County of New York maintains that the Code of Ethics is an essential part of the practice of medicine and it cannot be lightly discarded and any program that has for its purpose the extinction of the code of ethical conduct between physician and patient is destructive and against social welfare.

A Program of Development: It would appear that the time is not far distant when the County Medical Society must decide whether as an organization it shall enter into what may be termed the business of medicine. It is apparent that with our nearly four thousand members we have a sufficient clientele to seriously consider the establishment of an insurance bureau, or even an insurance company. It might also suggest itself that there could be formed and managed under the auspices of the County Medical Society a credit and funding society, a collecting bureau, and we might even go so far as to organize the personnel for the management of clinics.

It might be considered the proper function of the Bureau on Publicity of the Medical Society of the County of New York to devise and draw up a list of zones within the City so that persons inquiring for competent medical service could be given a list of properly qualified physicians, members of the County Medical Society residing or practicing within the zone and to make available to the inquiring public the names of certified specialists residing or practicing in certain designated zones.

I believe the Medical Society of the County of New York should endorse as a matter of policy the following:

1. A central registry for dispensary patients.

If a patient is accepting free medical service as a right, privilege or gift, of a city institution or a privately endowed charity, the community has the right to demand that that patient shall be registered and thereby prevent medical shopping and reduplication of labor and laboratory work, that are time-consuming and expensive

2 Adequate supervision of all hospitals—private, proprietary, semi-public and public Furthermore, the examination of all human tissue removed at operation by a properly trained and certified pathologist

3 The designation of hospital and dispensary zones This will embrace the entirely new conception of the role of the doctor and his place in the community It will involve the establishment of regional hospitals confined to a geographical area of the city, which will be the radiating point of information, the curative zone for the community Every physician in this geographical area shall have access to the hospital for his patients, arrangements may be made for x-ray and laboratory work for the private patients of the physician in the area

4 That the worthy poor be treated free of all charges

5 That as a result of the recent decision of Judge Samuel R Blake of the Superior Court of the State of California in and for the County of Los Angeles, in a case of Granville Mac Gowan, plaintiff, vs Medical Service Corporation a Corporation defendant, the Comitia instruct its counsel to bring suit against one of the medical bureaus engaging, as a corporation, in the practice of medicine, that this suit be pressed for a decision upon two fundamental questions (a) Can a corporation practice medicine? (b) Is the manner and method of the defendant corporation such as to constitute the practice of medicine?

6 That a special committee of your Society be instructed to undertake an investigation and survey with the following objects in view (1) to canvass the entire situation of the medical and dispensary practice in the City of New York, (2) that they consider the possibilities of the application of the insurance principles to this problem (3) that if possible they report by specific resolutions how the condition can be met and solved and (4) that the problem they are to study is primarily not a question as to who can pay or who cannot pay for individual medical services, but the broad fundamental problem of how payment can be made That they shall consider as a fundamental fact that all doctors working in dispensaries—public, private or corporate —dealing with medical service, shall be paid a fair remuneration in keeping with their education, experience and services

That the Committee consider and make suitable resolutions in regard to the zoning of clinics, the zone hospital, the central bureau of registration for free clinic patients, etc This investigation would probably take a year to two years, would probably require the expenditure of $15,000 to $25,000 and your President is firmly convinced that this laudable study could and would be financed in ample measure

The medical problems presented herein are common to all of the societies and the interest of the doctors in the five boroughs will be best served by setting up a coordinating committee composed of two representatives from each borough The purpose of this committee will be to familiarize each County Society with the activities of their neighbors, to recommend a program of activities common to all of them and to suggest the organization whereby these objectives may be consummated

Conclusions

These are my views and for the present I shall *hold to them I shall be prepared to accept other* views when they are brought forward and prove to be true views I shall modify my official opinion when it can be demonstrated that in so doing I can advance the cause of medical practice

The problem of medical charity confronts us It is a challenge to society I have great faith *in the intelligence the understanding and the* brains of our social and medical leaders I believe this problem can be settled adequately, effectively and with justice to all There is no force in the spoken or written word the power lies in the ideals and the personality behind it If under a comprehensive plan we can bring to this problem ethical and moral leadership there is the hope that we can provide adequate medical service for all groups of our people at all times and that social medicine may continue with increasing years of usefulness

Throughout our community there is a spirit manifest and a willingness freely expressed to help solve this problem As individuals we can contribute the best of ourselves our loyalty and our thoughts to make this a living, advancing ideal The time is opportune and we must address ourselves seriously to the interrogation that presents itself—society and the doctor We stand at the parting of the ways from an old outworn system to a new and better type of social organization There are difficulties They can be solved

THE TREND IN THE CARE OF THE SICK

By THE RIGHT- REVEREND JOHN FRANCIS O'HERN, ROCHESTER, N. Y.

A paper read before the 125th annual meeting of the Cayuga County Medical Society on December 9, 1930, by the Bishop of the Roman Catholic Diocese of Rochester, N. Y.

As the regard for the welfare of others is an evidence of fine character, so thoughtfulness of the people of a community—each for all and all for each—may be considered as one of the great civic virtues. In no better way may this thoughtfulness be expressed than in the care of the ill, the injured and crippled; in kindness for the mentally and physically distressed; in watchfulness of the infant; and in the care of the aged. In primitive times the mother was undoubtedly the only physician, the only nurse of the ill. Her concern for the well-being of her offspring prompted her to study ways of making them comfortable and better, and restoring them to the family circle, well. Her sheltering arms were the first hospital. In ancient times, even in the days of Greece, the deformed and the diseased newly born were exposed to the elements, and to the wild beasts of the land and of the air, that they might die; and among the very poor, the aged, it has been said, were driven forth from the home and left to die.

As civilization progressed, there came into being the fore-runners of medicine. Aesculapius, the reputed son of Apollo, was the god of healing, and his disciples cared for the sick in his temples. The ill sometimes slept in the temples and as a curative measure were allowed to witness the services or rites, and to make appeal to the god for the restoration of their health. No person was allowed to die in the temple; nor within its walls was a child born. About the temples, buildings were erected for the ill, the injured and the wounded, and for the women in labor; and a shelter for the dying was provided. It is said that Hippocrates, the so-called father of medicine, was born 460 B. C., in a building near the temple in the Island of Cos, to which his mother had been assigned; and as he grew up and made bold to teach the natural laws of disease against the view that illness was due to anger of the gods, or maliciousness of demons, it was from the temple that he issued his great teachings of the care of the sick.

Although there is no great evidence of institutions for care of the ill in Roman history, yet we learn that sick slaves of Rome were removed to an island in the Tiber; that Caesar removed the sick and wounded to quarters in town before a battle, and that chariots followed his armies to transport the sick and wounded to places for treatment.

It remained for the teachings of Christ to instill in the hearts of people a kindly regard for the ill and aged. We learn in Holy Writ that they came to Him and they brought to Him the lame and the blind, the sick and the leprous; and about Him they lay on pallets and stretchers awaiting the healing touch of His divine hand. And curiously it was about the shrines of the new faith that the people gathered in their quest of restoration of health; and it was in the infirmaries of the monasteries that in thousands dotted the countries of Europe in the early centuries of the Church, that there gradually developed a separate branch of monastic endeavor, in time housed in a separate building, that early was called a hospice.

Men and women banded themselves to care for the insane,—the Crusaders were the first to establish an institution for their care—the sick, the crippled and the aged; and in the Middle Ages, institutions marked by economy in administration were founded for those purposes. France in the Thirteenth Century had over 2,000 such establishments, and in 1456 the Grand Hospital of Milan, yet in use, was built, where patients from their rooms might join the service of the church said daily in the central court. The word hospice meant not only a place of welcome, comfort, and attention to the ailing, but also an institution where the spiritual welfare of the patient might be cared for. What a beautiful thought actuated St. Landry, bishop of Paris, to call the hospital founded by him in the Seventh Century the Hotel Dieu, God's house. Early in the Eleventh Century Canterbury's archbishop founded two hospitals, and within two centuries some of the most celebrated establishments for the sick in England, notably the Five Royal Hospitals, were built.

What a wonderful army of men, under vows to perform the corporal works of mercy,—visit and care of the sick,—labored in the institutions, caring for the people in time of epidemic, in the distress of war, and giving tender care and sustenance to those so often ill because of poverty.

This is the day of the hospital. Millions and millions of dollars have been given freely by the over-rich to establish these institutions, especially in our country, and millions and millions more of dollars have been generously given by the people, often by those of little means, not only to help build hospitals but also to maintain them. Three hundred million dollars have been spent in building

hospitals in one recent year in the United States, and today in this country three hundred and sixty-five million dollars a million a day, is the cost of maintaining them With in ten years there has been an increase of 125 per cent in the number of hospitals in the United States

In medicine this is the day of the hospital Within its walls are gathered the sick the injured, and those needing surgical attention for the instruction of the students of the various medical colleges of the country At the bedside of its inmates, the beginner in medical study receives instruction and demonstration of medicine and surgery by visual and actual experience And by his residence with the sick, the newly graduated physician has opportunity to witness the wisdom and skill of the eminent men of his profession and is given charge in many instances under the direction of seniors, of the patient himself

In civic advancement this is the day of the hospital Without it no community can be considered as progressing to a better civilization, advancing to that humanitarianism of the loving Father which returns a mother and her newborn babe to the home which restores the usefulness of its citizens, which gives back to industry in all its forms its laborers, which protects all, the rich and the poor against the advance of epidemic communicable disease, which guards the community at large against the vagaries and outbreaks of the mentally ailing, which restores to such a large percent of those thus afflicted by rest and tender care, their reason and returns them to the enjoyment of life

In the changes in social life,—and by this I mean a more equitable and fair adjustment of the relation of man to man,—this is the day of the hospital Man's inhumanity to man is being lessened, that each to a certain extent is his brother's keeper is being more recognized that the state, that it may have strong and valiant defenders in time of war and well and sustaining citizens in times of peace, should assure their well being through life to the grave, is now conceded We have today clinics for the expectant mother to receive instructions as to the proper care of herself that her child may be born well, and to which come

> "Babes, neath the hearts of mothers,
> tomorrow,
> Babes out the arms of mothers of
> sorrow"

The ill are no longer cared for in the home children are no longer born under the roof of their parents or grandparents and under the humane sections of the public welfare law recently in effect the indigent and the near poor of the community are entitled to hospital care and skilled treatment

In industry with all its ramifications, this is the day of the hospital Our very large industries pride themselves upon maintaining finely equipped hospitals with each of their big plants caring not only for the maimed and injured but instructing their employees in proper modes of living, even extending their services into the homes of their workmen All this means an early return to work restoration of the injured or crippled, and better care of those ill of occupational diseases

At last the state recognizes the value of the life of each of its citizens and has even placed an average value of over $5 000 on the individual And it realizes in order that it may get the greatest return from this valuation this human machine must be kept in good condition must be protected against accident, must be repaired in case of injuries or illness, and be restored to usual labor as soon as possible Authorities claim that the time absent from labor of those hospital treated is but a fraction of that of those home cared for and point with pride to the fact that the average stay of patients in hospitals has been reduced in recent years from 23 days to 12 days In this great country of one hundred and twenty five million people what a great economic saving alone is thus effected!

All this means that civicly, socially industrially and economically, the hospital has become a very necessary part of our modern life

Now what is the duty of the community towards the hospital and what must the hospital offer to secure recognition of its worthiness? It should be maintained, I might say sustained for today it is recognized as not only a place for people to go to that they may become well or better, but it is the center of health activities People come to the hospital for medical advice, for periodical health examination or check up for diagnosis, for instruction in prevention of disease as well as for the cure or alleviation of established conditions People should patronize their own hospital, and should gladly and promptly, if possible, pay for the service rendered, ap even in this day of economic stress t should give of their means towards its port Because of this stress our hosp today showing a greatly lowered l pancy, 64 12 being the per cent of reported by 2717 hospitals the past the hospital cannot very well redu sonnel or lessen any activity n

RESULTS OF THE LIVER TREATMENT OF PERNICIOUS ANEMIA*

By JOSEPH E. CONNERY, M.D., NEW YORK, N. Y.

From the Department of Medicine, University and Bellevue Hospital Medical College, New York University, and the Third (New York University) Medical Division of Bellevue Hospital.

IN 1926 Minot and Murphy (1) published an account of their results of the treatment of pernicious anemia by a special diet rich in liver. Forty-five patients were included in the study. One year later these authors published a second article (2) giving the results of the use of this diet in one hundred and five patients. The striking and almost uniformly good results of the use of the diet were shortly confirmed by many other investigators and a voluminous literature rapidly accumulated.

An account of the results of the liver treatment of pernicious anemia readily lends itself to consideration under three headings; viz., Changes in the results of the laboratory data; Results of the treatment on the subjective findings; and Results of the treatment on the objective findings.

Changes in the Results of the Laboratory Data

The feeding of adequate amounts of whole liver is followed in the course of a few days by an increase in the number of reticulocytes above the normal. This effect is absent only in the exceptional case. The beginning increase occurs about five to seven days after treatment is started. The height of the peak of the reticulocyte curve is inversely proportional to the level of the red cells. The potency and dosage of the preparation used are other factors which determine the magnitude of the reticulocyte response. Occasionally a secondary peak may occur or the order may be reversed and the major peak be preceded by a minor peak. The phase of increased peripheral reticulocyte activity extends on an average over a period of about twenty-one days.

Later the curves of the red cells and the hemoglobin increase with the level of the former usually rising more rapidly than the latter so that the color index falls below unity. In the course of two to four months after beginning treatment the values for the red cells and hemoglobin are within the normal limits. Failure of these components to attain their normal levels may mean inadequate dosage, incomplete taking of the diet or the presence of an infection. Quite rarely a patient is seen in whom, apparently, none of the above-mentioned factors operates whose red count either cannot be raised to the normal level or kept there if it originally had reached a normal value.

The curve of the total number of leukocytes rises usually to normal and occasionally above the normal level temporarily. The polynuclear neutrophiles take on a less complex nuclear pattern. In one of our patients who was treated with large initial doses of a potent liver fraction the total leukocyte count reached a level of some thirty thousand and the neutrophilic leukocytes showed a distinct shift to the left.

Early in the course of treatment the eosinophiles increase temporarily in some patients. This effect seems to be more marked when whole liver is used but may also occur when a potent fraction is administered. The platelets increase early and usually attain normal values.

In patients whose initial red cell level is low, the stained blood smear shows a predominantly oval macrocytosis. As hemotological improvement progresses the macrocytes become, more of them, round and later all but disappear.

As a rule the icterus index is increased above the normal during the exacerbation. The values frequently fall within the zone of latent jaundice or they may attain the level of clinical jaundice. The qualitative Van den Bergh gives a negative immediate direct reaction and a positive indirect reaction with the values for the quantitative determination increased. When liver is effectively administered the icterus index returns to the normal zone or even to a low normal level and the quantitative Van den Bergh figure falls to normal.

The urinary output of urobilinogen in our series of patients was found to be increased above the normal in about fifty per cent of the cases. As a rule the output of urinary urobilinogen quickly returned to normal after liver therapy was instituted. Transfusion was almost always followed by a rapid and marked increase in the output of this chromogen.

With one exception, noted below, none of our patients showed a return of free hydrochloric acid in the gastric contents at any time during the period of relapse or induced remission. The exception showed a return of a slight amount of free hydrochloric acid after a remission had been well induced and sustained for some months. The amount has always been small. Shaw, quoted by Minot and Murphy (2) reported a similar finding, as did Heeres (3).

Effects of the Treatment on the Subjective Findings

In the course of a few days after liver therapy has been instituted, subjective changes become manifest. These changes may begin before the phase of increased reticulocyte activity is seen in the peripheral blood and well before there is any striking change in the level of the red cells or hemoglobin. The patient feels stronger and ex-

*Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1930.

periences a sensation of increased warmth of the skin. The appetite improves rapidly and markedly, so much so that at times it may be said to be ravenous. Articles of food which were formerly purposely omitted from the diet, especially meat, are taken without discomfort and at times even with relish. Nausea and vomiting, especially the latter, are relieved early in the course of treatment. If diarrhea has been present the movements soon decrease in frequency and formed stools are passed in normal numbers. On the other hand, if their number and character have previously been normal, the stools may become loose after treatment is first instituted, but this effect is quite transient. Soreness of the tongue and rawness along the esophagus are relieved in the first few weeks of treatment. Occasionally evanescent attacks of soreness of the tongue may recur long after a remission has been induced even in the presence of normal hematological findings.

Symptoms directly referable to the anemia such as dizziness, headache, head noises, blurring of the vision, dyspnoea and palpitation, are relieved as the curves of the red cells and haemoglobin rise. Edema, frequently present in the dependent parts of the body, is usually relieved as the degree of the anemia lessens. Occasionally it may return in the ankles after the patient first gets up and about. In some few patients the edema may persist in the ankles and increase after the patient has been up during the day. Frequently varicose veins may be found in such patients.

Stiffness in the joints, especially hips and knees, or muscle soreness frequently in the muscles of the lower extremities or a feeling of tenseness of the skin may develop after the induction of a remission is well along, or all of these complaints may occur after the remission is well established.

Numbness and tingling of the fingers and toes, cramps in the calves, girdle sensations and paresthesias of the soles are usually relieved after liver therapy has been instituted. As a rule there is a restoration of manual dexterity so that fine movements can again be executed.

Many of our patients in the return follow-up blood clinic complain of attacks of numbness or tingling or both in the fingers or the toes even after months of normal hematological findings. As a rule, however, these attacks are almost never severe. Isaacs (4) has called attention to this recurrence of symptoms in patients with normal hematological findings and in those showing anemic changes.

Effects on the Objective Findings

In the course of a few days following the administration of adequate amounts of whole liver or a potent liver fraction, changes are noted in the color of the patients' skin; a faint but definite pale flush is seen. The lemon yellow color or bronzing, if present, soon fades. The visible mucous membranes become slightly pink. A skin formerly dry becomes moist. The eyes grow lustrous and the expression becomes alert.

Many of the patients exhibit a peculiar mental state in which either they do not comprehend what one is trying to do for them, or understanding, they are reluctant to cooperate. Coincident with the reticulocyte increase this mental state changes and, with few exceptions, a willingness and desire to cooperate ensue.

Occasionally a patient is seen whose tongue is red and clean but quite fissured after there has been a satisfactory response hematologically and subjectively. This condition has been seen in a few of our patients who showed no pronounced cord changes. Other observers however, have noted the occasional persistence of tongue changes in patients who showed moderate to marked cord involvement.

Practically all our patients exhibited a continued irregular temperature. Sudden and marked increase in the output of urinary urobilinogen was accompanied by a further rise in the temperature curve or by the appearance of fever if this was previously absent.

Murmurs of one kind or other heard over the precordium or the great vessels in the large majority disappear after the anemia has been relieved. This is the usual finding and is borne out in our series of patients.

In about twenty per cent of our patients the spleen was palpably enlarged. We could not demonstrate any apparent relationship between this finding and the height of the reticulocyte peak, or the icterus index, or the amount of urinary urobilinogen. In all our patients induction of a satisfactory remission was accompanied by a decrease in the size of the spleen so that this organ was no longer palpable.

The results of the feeding of adequate amounts of liver on the subjective and objective findings referable to the nervous system are summarized by Minot and Murphy (2) as follows: "Recently developed symptoms of injury to the nervous system have usually yielded more rapidly and satisfactorily than those due to long standing lesions. With few exceptions, patients have not developed neural symptoms, nor have they shown any extension or aggravation of such pre-existing lesions after they have been on the diet for a month." These authors noted four exceptions to this statement.

Isaacs, Sturgis and Smith (5) are quoted as follows: "The neurologic symptoms and evidences of degenerative changes in the nervous system seem to be benefited only secondarily when the blood count approaches normal, as there appears to be no direct action by the liver or liver extract on the diseased nerve tissue. Three patients in

our experience have developed neurologic changes after their red blood cell counts had increased to around five million per cubic millimeter."

Bubert (6) reported a patient with pernicious anemia and well marked subacute combined sclerosis who responded to liver therapy to such an extent that some of the deep reflexes returned.

Our experience regarding the effects of liver therapy on the objective neurological findings, in a smaller series of cases however, seemed to parallel that of Minot and Murphy as quoted above. In our patients who showed definite and even advanced evidences of subacute combined sclerosis there was no difficulty in raising the level of the red cells and hemoglobin to normal values. When this occurred no matter what the previous degree of physical disability, all the patients showed an increase in strength. Some, by means of diet, massage and muscular reeducation, were so improved that they could be up and about with or without the aid of a cane or other means of support. Others either remained bed-ridden or, at best, could be about only in a wheel chair. This occurred in spite of the fact that a comparable degree of hematological improvement was effected in both groups of patients. A point to be stressed is this—that the neurological status, when the patient first comes under observation no matter how advanced the involvement, does not necessarily furnish an index of the degree of restoration of function that can be effected when adequate amounts of liver are adminstrated, supplemented by massage and muscular reeducation.

The onset of the disease in one of our patients, a man in his late twenties, dated back about three mounths and was ushered in by findings almost entirely referable to involvement of the nervous system. On admission he showed only a mild degree of anemia. The neurological examination, however, revealed the presence of well advanced subacute combined sclerosis. Because of the apparent rapidity of the progress of the neurological involvement, large doses of a potent liver fraction were administered. The usual hematological response occurred and the red cells and hemoglobin were increased to normal values. The neurological involvement, however, continued to progress. Liver fraction medication was discontinued and massive doses of whole mammalian liver substituted. The progress of the neurological involvement was stayed. When the patient was first admitted to the hospital, walking was impossible. On discharge he was able to get about with the aid of a cane. Improvement has continued so that he is now able to walk with a facility and confidence that hardly seemed possible when he first came under observation.

In none of our patients have we been able to demonstrate a return of the deep reflexes. Impairment of position sense has been improved in some. A return of vibratory sense has never been completely effected in any instance, where this has previously been completely lost. Mild degrees of impairment of this sense have frequently been improved.

The results of liver treatment on the neurological involvement have been discussed at some length because it would seem that if criticism is to be leveled at the liver treatment of pernicious anemia, the attack would be at this point.

Results of the Treatment During the Stage of Induced Remission

Patients have been observed whose red cell counts and hemoglobin values have been maintained at normal levels for periods well over two years. In some instances after normal quantitative hematological values have been restored there is an unexplained fall of the red cells below the normal level. Such patients have been few. Mild infections as a head cold or a slight sore throat frequently reflect themselves by a definite fall in the number of red cells and the level of the hemoglobin. An attack of diarrhea may precede a decrease in the number of red cells or the numerical fall in red cells may usher in the attack of diarrhea.

Numbness and tingling in the fingers or toes, especially the former, recur rather frequently. The duration of such attacks is not long and the severity not marked. Patients sometimes complain of burning or rawness of the tongue, but again as a rule, not to such an extent as to be seriously annoying or incapacitating. A feeling of epigastric discomfort occurs occasionally.

Stiffness in the joints or soreness of the muscles coming on after a period of inactivity and relieved by exercise may first appear after a remission has been well established. These may occur whether the patients take a liver fraction or whole liver.

Conclusions

A return of normal quantitative haematological values may be expected in all but the exceptional case following the use of liver or a potent liver fraction.

Persistent absence of free hydrochloric acid continues to be the rule.

Subjective and objective findings directly dependent on the anemia are relieved as the blood findings approach normal.

In all but the most advanced degrees of neurological involvement some improvement may be expected and even in this group the outcome may not be so hopeless as first observations would seem to indicate.

In patients previously doing well, who show a fall in the level of the red cells and hemoglobin, laxity in taking the diet should first be suspected. If this factor can be eliminated the presence of an intercurrent infection is the next most probable explanation.

X-RAY TUBERCULOSIS IN APPARENTLY HEALTHY INDIVIDUALS*

By ADA CHREE REID, M D, NEW YORK, N Y.

THE results reported here are based on experiences that we have encountered for the past three years in the course of examinations of applicants for employment at the Home Office of the Metropolitan Life Insurance Company in New York City

Since October, 1927, we have fluoroscoped the chests of all such applicants after a complete physical examination in order to detect, if possible, tuberculosis that had escaped the physical examination It had long been a source of chagrin that in many of these young people, advanced tuberculosis would become noticeable soon after they had had a physical examination and had entered the employ of the Company, so soon in fact that it was safe to assume that in many cases the disease was present at, but had not been detected by, physical examination It was first suggested that all pre employment and annual examinations should include a single roentgenogram of the chest but this was considered too expensive an experiment to be undertaken without trying other methods of examination first However, it was felt that a careful fluoroscopic examination would detect tuberculosis in the advanced stages and possibly also before it had become advanced It is not a new idea that pathology of the lungs may exist without giving abnormal physical signs, but so often when we advise our employees or applicants of their positive x-ray findings, we are told that their own physicians have just examined their chest, have heard nothing wrong, and therefore they do not have tuberculosis, that we feel obliged to stress the point We do not find it mentioned in the textbooks but in the current literature it is emphasized frequently

Lawrason Brown states that "tuberculosis occurs so often without any definite physical signs that I never exclude pulmonary tuberculosis until I see the *x*-ray plates" Austrian writes, "Roentgen-ray may disclose a causal focus of symptoms in patients in whom physical examination fails to discover it" The same opinion is expressed by Heise, McPhedran and Rathbun Physical signs of significance may be absent in the more advanced stages as well Dunham states, "Tuberculous caseous bronchopneumonia may exist in a large area without causing any signs" The same is true of cavities Bendove reviewed 145 cases with definite pulmonary cavitation and concluded that "50% were silent, of which about one third are absolutely mute"

Soon after we installed the fluoroscope we began to discover cases of tuberculosis without symptoms or abnormal signs The first slide I am showing is of a healthy young Polish woman applying for a position in the Commissary Department She passed the physical examination but the fluoroscope revealed a cavity in the right lung She was sent to the Tuberculosis Clinic at Bellevue re examined, and the absence of physical signs corroborated

The next slide is of a very attractive young girl of Irish parentage, with no physical signs but a moderately advanced tuberculosis on x-ray Again the absence of physical signs was confirmed at Bellevue

The next two slides are of two of our own employees, who were fluoroscoped at their annual examination In both of these cases we are certain that there were no symptoms and the absence of physical signs was checked by the examining physicians at our Sanatorium at Mount McGregor

We mentioned earlier that we hoped with the addition of the fluoroscope to detect advanced disease and possibly tuberculosis in its incipiency Soon after the inauguration of the experiment, we found that we were discovering many very early lesions as well The following slides are illustrative

Lantern slides showing early cases of tuberculosis

We feel that our success in the use of the fluoroscope is due to the fact that in each ex-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester N Y June 3 1930

amination we follow a definite routine, a description of which is appended.

It is our opinion that after a short period of instruction in the use of the fluoroscope, any physician with normal eyesight, will be able to detect lesions as early as those just shown. In the beginning of our experiment we had two trained fluoroscopists. Later we installed two more fluoroscopes in the examining rooms. Our staff of 16 physicians, after a short period of instruction in the use of the fluoroscope, began to fluoroscope routinely all applicants as well as to make a fluoroscopy of the chest of our own employees at their annual examination and the number of new cases of tuberculosis discovered in this way compared favorably with the period during which the trained fluoroscopists alone had made the examinations.

On the basis of the *x*-ray films just shown, we feel that we are justified in claiming that tuberculosis may be discovered in an early stage by means of the fluoroscope. One might question the propriety of rejecting apparently healthy applicants on *x*-ray evidence alone and in anticipation of this we have been able to re-examine about 50% of those in whom we recommended rejection, in order to determine the progress of the anatomical lesion. Of those re-examined, 58% showed progressive disease either by *x*-ray increase or symptoms of activity. This slide is that of a young lady of 22 years who applied for a position, was examined in the usual way, and the chest was considered negative. The fluoroscope, however, revealed a small calcified area in the right apex. We advised her to consult her own physician and have periodic examinations, but this she apparently did not do because 9 months later she returned to say she had had an attack of grippe and was not feeling well. Physical examination then revealed an advanced tuberculosis and she is now curing at Saranac Lake.

A somewhat similar case is the next; a basal tuberculosis that was progressive and this girl was admitted to Trudeau.

The same experience in detecting so-called silent tuberculosis was repeated when we came to fluoroscoping our 10,000 Home Office employees at their annual examinations. We found in the first year, 70 cases of whom 37 were age 35 or over, with apparently healed *x*-ray lesion, present lack of symptoms and past history of good health. These were allowed to remain at work under observation. The second group comprised 21 employees who were considered as pre-clinical or "ready to break," and went immediately to our Sanatorium at Mount McGregor. The remaining 12 had no symptoms nor signs as far as could be ascertained by temperature curves, blood counts, and careful history taking and yet since they are of the adolescent and young adult age, 16 to 34, they have not had the test of time or of work and cannot, therefore, be placed in Group 1, the apparently healed class. They have all been advised to spend a short period at the Sanatorium where they may be under close observation and where they have the benefit of Sanatorium instruction in the rules of health. It was during our observation of these latter employees, preliminary to their admission at the Sanatorium, that we observed another important feature of the disease, namely, that there may be definite anatomical progression of the disease as shown by *x*-ray and an entire absence of symptoms and physical signs.

The following slides are those of an illustrative case. J. H., a young man of 19, at his annual examination, July, 1929, was found to have a moderately advanced tuberculosis on *x*-ray. Signs and symptoms were absent. He was advised to go to our Sanatorium, but postponed his departure one month. During this time he took particularly good care of his health. In August, 1929, he was *x*-rayed again; there was a definite increase in the infiltration, but again there was an absolute lack of physical signs of symptoms.

When we, in the beginning, decided to recommend rejection on *x*-ray findings, our basis of rejection was a definite parenchymatous lesion. It was agreed that we would not reject on increased peritruncal markings nor on signs of the healed childhood type of tuberculosis alone. The latter group we have *x*-rayed every 6 months from the date of their employment.

The next slide is that of a young girl, age 19, at whose entrance examination the fluoroscope revealed a healed primary infection. Subsequent *x*-rays showed no change. At the time of her second annual examination she had gained 19 pounds since her employment, but the *x*-ray at this time revealed a definite incipient tuberculosis; this, in spite of the fact that an *x*-ray 6 months previous had shown no change and she had since that time gained 12 pounds in weight.

To summarize the results of our observations of tuberculosis among a large group of industrial workers, of whom the vast majority are adolescent females, we find that,

(a) Of those applying for employment, 1.21 per cent had *x*-ray evidence of disease without physical signs or symptoms. Of these over one-half showed progressive disease within the year.

(b) The application of the fluoroscope as an adjunct to the annual physical examination of our Home Office employees has revealed 0.7 per cent of silent tuberculosis, of whom those who are apparently healed have the benefit of careful observation; those who do not fall in this group had the benefit of Sanatorium treatment before the onset of symptoms. Upon comparing the number of cases of tuberculosis diagnosed during 1927, 1928 and 1929, we find the following:

TABLE I

In other words, out of every three cases at present diagnosed as tuberculosis two are being discovered before the onset of clinical activity The total figures also show a considerable decrease in the total number of new cases diagnosed among the Home Office employees which would seem to indicate that by the methods described above, we have our tuberculosis problem under much better control than ever before

We have shown cases of tuberculosis which were progressive under observation even though physical signs or symptoms of disease have been absent

Conclusions

It is possible to demonstrate pulmonary tuberculosis in many cases in its incipiency as well as in the advanced stage with the fluoroscope Pulmonary tuberculosis may be present in the absence of physical signs or symptoms There may be a definite anatomical spread of the disease without suggestive symptoms or definite physical signs

No examination of the chest may be considered complete without the aid of the *x*-ray

†Figures for the entire year 1930 have been added At the time of the original report, only those of the first four months were given The report is even more favorable than was anticipated at that time

x Of these 43, 18 were fluoroscoped and on the basis of these findings, were sent for X-Ray

Technique of Fluoroscopic Examination of the chest as routinely carried on at the Home Office of the Metropolitan Life Insurance Company, Medical Division

The use of the fluoroscope is a potential source of danger but if the ordinary rules of protection for operator and patient are observed there should be no untoward effects The ordinary rules include the following, namely, a machine which is well grounded, wires which are out of reach of patient or operator, a lead rubber protection either as an apron suspended from the bottom of the fluoroscopic screen or a lead rubber apron covering the body of the operator Lead rubber gauntlets should be worn in making every examination The machine should be installed in a room which may be completely darkened

We use a standard instrument with a 5 inch spark gap at 110 volts and 5 milliamperes The time required for a complete examination varies from 2 to 3 minutes

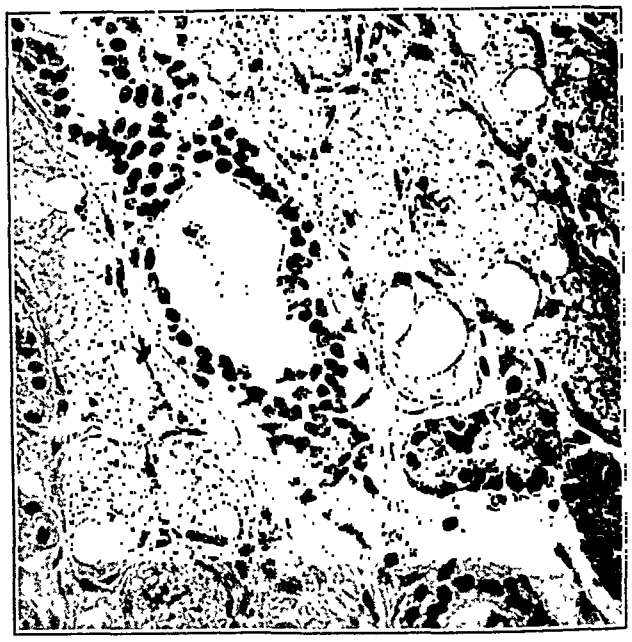
The physician waits in a darkened room until his eyes are sufficiently accommodated, usually, 2 to 4 minutes, then views the chest in the following sequence, first, the chest as a whole, comparing right and left sides as to contour, size and movement, next the mediastinum and its contents rotating the patient so that the posterior mediastinum is examined, and then the diaphragm, noting contour, freedom of motion on quiet and forced respiration, and then the costophrenic angles

In inspecting the lung fields the diaphragm of the instrument is closed so that only an area equal to one interspace is seen—the right and left sides compared for difference in transmission of the ray The supraclavicular muscles are pushed aside with the gloved hand giving a clear view of the apices The patient is told to hunch his shoulders, thus bringing the apical fields into view above the clavicle To obtain a view of the first interspace the arms are internally rotated so that the palms are facing outward Each interspace is subjected to the same careful scrutiny Rotate the patient slightly to the right and to the left—in this way very small lesions have been picked up Then the patient is turned around and the same procedure is followed (The value of this was appreciated after the demonstration of a small lesion near the anterior chest wall which was not seen until viewed from the posterior aspect) Finally, the patient again faces the operator and with the eyes at their optimum accommodation, a last look is given at the apices and upper lobes

A CONGENITAL CAPILLARY ANGIOMA OF THE PAROTID GLAND

By M. J. FEIN, BROOKLYN, N. Y.

From the Pathological Department, Cumberland Hospital, Brooklyn, N. Y.



IN an article that recently appeared in the *Archives of Pathology*,[1] Doctor Joseph McFarland of Philadelphia reported a case similar to the present subject. He remarked that this type of angioma was "a rare and interesting tumor of the parotid region," in reporting the thirty-fourth case on record. The termination of the three years' limit allowed for recurrences, justifies my placing this case on record as the thirty-fifth to be published.

Report of a Case: This was a well developed child eight months old, with a swelling that dated from birth, on the right side of the jaw over the parotid region. The skin covering the region was smooth and not attached, freely movable and not discolored. The mother had noticed that the swelling increased when the child cried. No pulsations could be felt. The pre-operative diagnosis was a mixed tumor of the parotid gland. The gland was removed in September, 1927, and it was easily shelled out. The recovery of the child was uneventful; after three years there seems to be no recurrence.

Macroscopic examination revealed an extremely vascular mass, round, soft, which measured about five by three centimeters. It was well encapsulated, and in portions showed the definite lobules of the parotid gland. There were no extremely hard areas nor cysts. It must be admitted that the biopsy offered a rather doubtful interpretation, and I passed it through with a tentative diagnosis of a simple hypertrophy of the gland or possibly an angio-endothelioma.

On microscopic examination, the specimen appeared to be a parotid gland with lobules that were encapsulated and appeared normal. The pathological lobes were atrophied, with many dilated vessels, irregular in contour, which had replaced many of the lobules. In the pathological lobules a few dilated acini were seen between the dilated capillaries, but most of them were small and crowded together. Their cells were not so high, and only the excretory canals seemed to have preserved their normal character. The diagnosis was Capillary Angioma of the Parotid Gland.

Comment: In the year 1889, Henri Hartman[2] described the case of a girl baby five and one-half months old, who presented a tumor of the parotid region measuring about five centimeters in its vertical diameter, and four centimeters antero-posteriorly. The tumor was soft, depressible, somewhat fluctuating, and partially reducible. There were no functional symptoms and the child was otherwise in good condition. Hemorrhage was abundant. The case could not be followed, but proved to be angioma of the parotid gland. In the literature, Hartman then found three cases very similar to this, all examined at autopsy: one by Tenon, published in 1841; one by Berard, and the third by Abraham Duke, in 1842. None of

these cases had microscopic examinations, but Hartman was quite sure these would have proved to be identical in character with the type he described.

Gascoyon[3] in 1860, reported a man of forty-four with a congenital parotid tumor which finally increased to such a size as to cause death by suffocation. At autopsy, numerous nævi were found in the intestinal serosa, one on the submucous tunic, one in the liver. The parotid tumor presented enormously dilated and sinuous vessels which had been transformed into great pouches, finally forming cavernous tissue with phleboliths.

Teale,[4] exhibited to the Royal Medical Society, a nævus of the right parotid removed from a child of eight months.

L. S. Pilcher,[5] removed from a baby only six weeks old, a large tumor of the left parotid which had grown with great rapidity since birth. The facial nerve was cut during the operation, producing paralysis on that side. Histological examination by Doctor Charles Jervett showed the tumor to consist of a mixture of glandular tissue, normal in character, and of cavernous tissue.

Augier[6] reported in 1907 a diffuse angioma of the parotid gland in a baby seven months old, on the left side. The angioma had begun to grow rapidly although it had been present since birth.

The tumor was removed without much trouble. The mass suggested a glandular hypertrophy, and on microscopic examination the author concluded that this was a simple angioma, as the vessels were normal in construction though diffuse and hypertrophic.

PULMONARY HEMORRHAGE WITH UNUSUAL SEQUELÆ*

By EARLE E. MACK, M.D., SYRACUSE, N. Y.

This man is thirty-two years of age, is married and has three children. His general health has always been good and he has had no serious or long-confining illnesses.

About three weeks prior to the onset of the illness about to be described, he noticed that he tended to tire easily, and that this fatigue was attended by excessive sweating. A harsh, irritative and non-productive cough had been present for several weeks, but had tended to become more persistent during these latter three weeks.

The acute clinical symptoms developed one evening after the patient had retired. He stated that he had coughed quite persistently during the day and had felt that he might be relieved if he could get to sleep. He was unable to sleep, however, the cough becoming more paroxysmal in character until finally, following an especially severe attack, he coughed up what he felt to be a fairly moderate amount of blood.

When seen about one-half hour later, he was still coughing considerably and was found to have a mouth temperature of one-hundred degrees. It was estimated that he had expectorated between two and three drams of blood which appeared to be quite a bit darker than that usually seen in the ordinary case of hemoptysis.

Morphine was administered hypodermically for the control of cough and restlessness, and physical examination of the chest temporarily postponed, especially because of the fact that changes in posture tended to cause a return of the paroxyms. Following the use of the anodyne, the patient rested fairly well during the night, coughing only when he attempted to talk. No further hemoptysis occurred.

Complete bed rest was advised, and was found to be the most satisfactory way of controlling the cough. Aside from the latter which returned at fairly frequent intervals, the patient had no other complaints, although for the next few days the temperature ranged from one-hundred to one-hundred and two degrees.

Physical examination of the chest was made daily, but no abnormal physical signs were detected until the fourth day, at which time a small area of dullness about two inches in diameter was detected near the angle of the right scapula. Auscultation over this area revealed no adventitious sounds.

With pulmonary tuberculosis a first thought, the possibility of a central pneumonia had also been considered, and with this finding the suspicion increased.

The temperature continued to remain elevated, and on the evening of the sixth day after the onset, rose to one-hundred and four degrees. On the following morning the patient was brought to the hospital for further observation and x-ray examination. On admission his pulse was one-hundred and twelve, the respirations twenty-four, and the temperature one-hundred and two and two-tenths, rising later in the day to one-hundred and three and eight-tenths.

The blood examination on admission was as follows:

Hemoglobin	80%
Erythrocytes 4,000,000	
Leucocytes	20,500
Polymuclears	72%
Mononuclears	27%
Eosinophiles	1%

The urine was normal.

A chest plate was taken on the afternoon of admission and, on the following morning, one glance at the roentgenogram shown made the diagnosis evident. (See Figure 1.)

The Roentgenologist reported as follows:

"X-ray examination of the thorax shows shadow of increased density in the right upper lung field at the periphery, apparently with cavity and fluid level. Diagnosis: Lung abscess."

With this hitherto unexpected pathology coming to light, an attempt was naturally made to explain the etiology, and it was at this time that we recalled the fact that the patient had submitted to a tonsillectomy seven weeks before, general anesthesia being used.

While it was obviously impossible to prove that the tonsillectomy had been the cause of this abscess, it offered the most logical explanation, especially when we consider the claims of some au-

* Read at Clinical Session at St. Joseph Hospital Annual Medical Alumni Reunion, Syracuse University, College of Medicine, June 6, 1930.

thorities, that abscesses which follow operations, including tonsillectomy and those on the head and

FIGURE 1

throat, may not be recognized for months. That this abscess had been present for quite some time would be indicated by the fact that the inflammatory zone about it was unusually dense.

Because of the thickness of this zone and because of the situation of the abscess well out near the periphery of the lung, it was felt that the case was not an ideal one for bronchoscopy, and would undoubtedly have to be treated surgically. However, recalling that the earliest clinical sign had been hemoptysis, and feeling that without any doubt this blood had been derived from the abscess cavity, it was reasoned that it might be possible for the encapsulated pus to escape in the same manner.

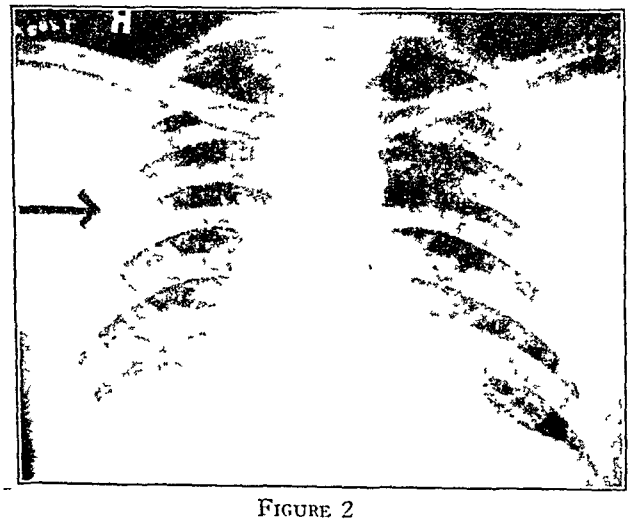

FIGURE 2

The technic of postural drainage was explained to the patient who was advised to lie upon the sound side as frequently as possible. He was instructed to lean well over the left edge of the bed at frequent intervals with the head close to the floor; the lower rungs of a straight bedside chair being firmly grasped with both hands to prevent falling. This manouver was employed for a few minutes at a time, and especially during the paroxysms of coughing.

During his fourth day in the hospital, which was nine days after the hemoptysis, the patient suddenly expectorated a moderate amount of grayish, mouldy-smelling purulent material, which was the first specimen of sputum we had been able to obtain since the onset of the illness.

On this same day the temperature fell from 102.8 degrees to 100. The postural drainage was continued, and while small quantities of purulent sputum continued to be expectorated, at no time was there any large quantity obtained, or at no time was blood again noticed in the sputum.

Two days later the temperature rose slightly again to 102, and on the following day fell to normal where it remained throughout the period of hospitalization.

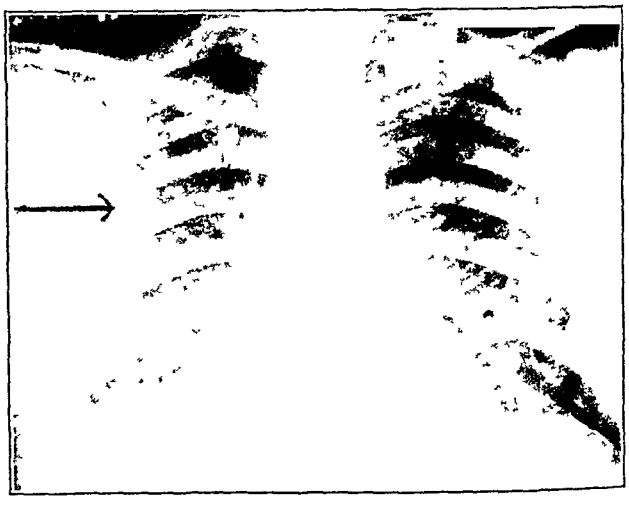

FIGURE 3

The material first expectorated was reported as showing a Type Four pneumococcus, and several additional specimens examined for acid-fast bacilli were reported to be negative.

Five days after the spontaneous evacuation of the contents of the cavity a second blood count was taken which showed a fall in leucocytes from 20,500 to 10,300. 61% were polynuclears, 36% were mononuclears, and 3% eosinophiles

Eleven days after drainage had been established, a second chest plate was taken. Concerning this the Roentgenologist says:

"Marked improvement and recession of the abscess in the right lung field. Cavity smaller—less inflammatory change around it." See Figure 2.)

Fifteen days after the onset of the illness, the patient was back at his home, and two weeks later was able to resume his regular work, making his period of total disability about four weeks in all.

One month after his discharge from the hospital the patient returned for a check-up, and the very satisfactory end result will be seen by a study of the third figure. (See Figure 3)

The patient has been under observation at very frequent intervals during the past few months, is symptom-free and feels exceptionally well.

Conclusions

1—The development of pulmonary symptoms following tonsillectomy should immediately raise the question of impending abscess of the lung.

2—Abscesses, especially those which follow operations on the head and throat, may not be recognized for months.

3—Without x-ray and with spontaneous evacuation of the purulent sputum, an abscess may escape recognition entirely, the case being erroneously diagnosed as acute bronchitis or bronchiectasis.

4—The contents of some of the more chronic cavities may not have the markedly fetid odor usually described in the texts, but may be almost odorless, a fact explained by the dominance of molds rather than bacteria.

5—Cough is present in all cases but varies greatly in intensity. When the abscess is single and of some size, a violent paroxysm of coughing usually accompanies the rupture into a bronchus.

6—Pure blood may be expectorated, but rarely in large amounts.

7—Postural drainage is deserving of first consideration, provided the patient is not apparently becoming worse.

8—An unfavorable location, namely at the periphery of the lung, does not preclude the possibility of escape of contents through a bronchus.

9—Following complete evacuation, healing may be quite rapid and complete.

AN APPRAISAL OF PRESENT DAY METHODS OF RAISING CHILDREN

FRANK VAN DER BOGERT, M.D., SCHENECTADY, N. Y.

At the recent meeting of the British Medical Association held at Winnipeg, Doctor Robert Hutchinson, whom many of you know as a distinguished English pediatrician, raised the very pertinent, yet rather astounding question as to whether the children of the "good old days of mud pies" were not happier and healthier than the oft-weighed, pampered dieted and psychoanalyzed infants of today. If what they did not know did not bother them both they and their parents were undoubtedly happier and if a little knowledge is as dangerous a thing as it is conceded to be they were certainly, on the whole, healthier. Some very definite dangers, at least, they were to a great extent free from; the money-mad exploiter, the over zealous nutrition worker and the medical educator of the public, not to mention the tonsilotomist and the pediatrician.

To be sure many of them died but there is no evidence that the fadism of today would have saved them. Too many factors have entered into the reduction of infant mortality to justify attributing it to any one cause, and in fact, the developments responsible for its gradual accomplishment had become operative long before the advent of what we call modern methods. Steadily improving prenatal care, encouragement of breast feeding and the attainment of a clean, simple and balanced method of feeding artifically under improving hygienic conditions were all playing their part and were beyond criticism.

Then too, unless we can insure those that we save a fair degree of future comfort perhaps it is better, as some believe, that they should not be saved at all. Nothing can be much more cruel than to completely protect a weakling from those distressing contacts, physical or mental, from which inevitably the protection must some day be withdrawn. Better risk death in the hardening process. Biologically too, it is unwise to breed a race of weaklings.

No thinking person can question the need of a preventive medicine but to be preventive it much be rational, directed toward a development of resistance. There are no short cuts to lasting health. Our milk enthusiasts would have us believe that a quart of milk a day is all that is required for perfect physical development. The tonsil has come to be looked upon, by the laiety at least, as the cause of practically all the ills of childhood and its removal is expected to be followed by permanent and perfect health. Nutrition has come to be a question of the number of calories swallowed, the fact that a calorie is merely the amount of energy produced under proper conditions of combustion in a healthy digestive system being completely overlooked. A vitamin is expected to provide for a deficiency whether assimilated or not. Moreover, more is expected from inoculation against specific diseases than can ever be attained. The experience of the army during our generation has clearly shown that attack against the single organism is in the broad sense ineffective. During the Spanish war, typhoid decimated the troops; a preventive vaccine was found, but upon the massing of men for the World War another organism arose and

* Read at the Meeting of the Fourth District Branch of the Medical Society of the State of New York, at Saranac Lake, N. Y., on October 16, 1930, and at the Meeting of the Rensselaer County Medical Society, at Troy, N. Y., on Nov 11, 1930.

caused even greater havoc. There seems always to be a new infecting agent rising to take the place of its defeated predecessor.

The hope of preventive medicine lies in the development of a resistant physical and mental makeup sufficiently strong to dominate the whole field, and such resistance can only be attained by playing the game, by meeting obstacles and overcoming them. What we all really want to do is to disregard the laws of nature and, when injury occurs, to resort to some simple expedient or some possibly not so simple operation to repair the damage, but it can't be done. As Peyton Rous suggests in his "Modern Dance of Death" anyone who is near the tap will use a tooth brush but it requires more fortitude than prevails today to avoid too ardent and exhausting living. The mother of one of my patients recently replied to a very optimistic prognosis that her child would not want to live if he had to follow my regime.

The control of specific infections has rendered the children of today less susceptible to these infections but at the same time it may well develop a false sense of security and a relaxation in the observation of those laws of nature which make for a general resistance. It would be delightful if our children's troubles could be limited to a few pricks of the needle although they themselves might prefer more of a less acutely painful nature.

The discovery of what we call vitamins has been of immense value in the prevention of deficiency diseases; these diseases have been very decidedly on the decline during recent years, but the damage that has been done by misdirected efforts to supply them have very probably to a great extent neutralized their beneficial effects. I do not refer to the danger of over-dosage so generally discussed just now in relation to irradiated ergoserol because I believe it problematical.

Interest in vitamins was enlivened by the development of the machine age. Our ancestors did not worry about vitamins, not only because they did not know about them, but because the refinement of foods did not deprive them of them. Unquestionably our knowledge of their importance has prevented a great deal of suffering but we should beware that in our over-zealous efforts to supply them we are not causing future trouble.

Probably there is no greater absurdity than the constant counting of calories. Food does not contain calories but is simply capable of being converted into calories under proper conditions of digestion. To feed a child upon the basis of calories without regard to the condition of his insides is as absurd as to coal a furnace without regard to its grates. To introduce potential calories in a form which may injure the digestive [illegible] as is commonly done by allowing large [illegible] of sugar, ice cream and other sweets, [illegible]ble, wholesome foods are refused, and to encourage the consumption of any food by camouflage, is sure to end in disaster. Unfortunately our nutrition experts tell us how many calories we need but they fail to tell us that in order to produce those calories we must digest our food. As a pediatrician the only need that I have found for the caloric method of feeding under normal conditions has been to determine whether I am over or under feeding after the diet has been decided upon.

How much better it would have been if nobody had compiled a weight-height table. Think of the low cost of education and the amount of mental suffering spared the parents. Only the milk producer would have lost and he would not have realized it.

Without wishing to appear unappreciative of the good that has come of medical school inspection I can not but condemn the unintelligent nutrition program still carried out in many school systems. To consider every child who does not conform to a weight-height standard, a standard which has been proven to mean little, a potential invalid; to distress him and his parents by telling him so; to remove his normal or, at least, not proven abnormal tonsils and to feed him more when he almost invariably needs less does not seem intelligent practice, and should not have its origin at the seat of learning. Dr. Fruhwald, whose recent criticism of American doctors may not have been very graciously received, is reported to have said that he doesn't believe there is a tonsil left in America.

How can our children be healthier and happier than those who though, perhaps, not guided, were at least not misled? Recently a teacher of children argued that one of my patients should be permitted the mid-morning lunch because of sociability, the very reason which led some of our citizens to insist upon the enactment of a prohibition law.

Despite all the wonderful advances in the medicine of childhood, I believe that the youngsters of the older time were possibly better human specimens, both physically and mentally, because they were not exploited by the efficiency expert and commercialist; they were not deprived of their vitamins by a machine age and supplied them unintelligently by the over-zealous; they were not stuffed to the distressing point because someone had misinterpreted the calorie and they were not on a mass production basis, required to meet specifications.

Medical education of the public has, I believe, been productive of much more harm than good. In enlightening the public a distinction should be made between hygiene and medicine. A rational knowledge and practice of hygiene is essential to healthy and comfortable living and can be imparted to all in intelligible language, but to make generally available or rather force upon them just

enough science to encourage misinterpretation will never lead to a better medical situation The slaughter of the innocent tonsil has been in great part due to the demand of the people who know ing only that it may occasionally cause disease think it will always cause it, who being told that it has no known function demand its removal There are those who believe that inoculation against a specific disease will prevent all diseases and, as I have before suggested nutrition to most of them is only a question of vitamins and calories, height and weight

The children of today, then, are at the mercy of the masses led by over-zealous and unthinking setters of fashion Although I make my living in the practice of pediatrics I honestly believe that they deserve a certain amount of protection from the pediatrician, the nutrition worker and the psycho analyst, as well as from the propagandist and the exploiter, and should be permitted to live a rational and not too carefully guarded existence, which may be summed up to include three simple meals daily, the discouragement rather than the encouragement of the bite between meals, the withdrawal of food when the appetite is lost rather than its forcing in a misdirected effort to improve nutrition, plenty of time for exercise in the open air and school hours adjusted to play, outdoor living and meals rather than the reverse as is now the case Let us forget the weight chart and estimate physical and mental development by the general appearance of well-being, the disposition or reaction to surroundings, the susceptibility to fatigue and to infections and by the progress up or down in the physical scale

The obligation of the pediatrician and of the general practitioner should be to prevent over doing, unnecessary and unwarranted treatment, to stand between the child and the over enthusiastic specialist, whether lay or medical, to see to it that in their efforts to justify their specialties they do not swing the pendulum to the breaking point

I am sorry that I can not agree with Dr Hutchinson in his criticism of the periodic health examination I am sure that, in the case of the child at least, many conditions, if found early enough, may be corrected, although it is very probably true that there is a great deal of non sense about the beginnings of disease in adult life and that many of them can not be detected early and if detected can not be cured Periodic examinations in infancy or early childhood are often worth while if for no other reason than to assure a mother whose nervousness and worry may distinctly react upon the child

---

A COMPARISON OF THE ROENTGEN RAY WITH OTHER FORMS OF RADIANT THERAPY IN TREATING SKIN DISEASES*

By HERBERT H BAUCKUS, M D, BUFFALO, N Y

IN making a comparison of clinical results obtained by various means of treatment, much of course in the deduction, depends upon the viewpoint of the observer The observations, here presented are entirely personal and were made by the writer and his associate, Dr W F Hoover, in dealing with more than five thousand cases of skin disease occurring in private practice during the past four years, in which Roentgen ray, Radium or ultra-violet ray were used In but a very small percentage of cases did the treatment consist of the use of these agents alone, but other therapeutic measures were employed when they seemed indicated In other words, radiant therapy was usually employed as an adjuvant to other procedures in the effort to bring about cure, or to relieve symptoms The writer believes that the above is an important attitude for the dermatologist to assume Perhaps we will try to be a little more accurate in our original diagnosis and use a little better judgment in selecting treatment if we are not so quick to "turn on the light" However, the fact remains that for alleviation, or cure, radiant therapy in some form or other is used to treat a very large percentage of patients that consult the dermatologist

Most of our cases were treated by Roentgen ray or ultra-violet ray, often by both The Roentgen ray was used in preference to radium except where the location of the lesion was more accessible to radium or where it was felt that the radium would effect a superior clinical result Lesions of the mucosa and the muco-cutaneous junction are usually more conveniently treated by means of radium The so called soft corn, (which is really a plantar wart), situated between the toes, is a lesion to which radium can more easily be applied Where radiant therapy was employed, we used radium exclusively to treat the various types of angiomatous nevi This type of nevus was the only kind where radiant therapy was followed by good clinical results We thought that the pigment which often occurs early in, or precedes, the various kinds of keratoses, was

* Read at the Annual Meeting of the Medical Society of the State of New York at Rochester N Y June 3 1930

more effectively treated with good cosmetic result by *x*-ray than by radium. Possibly this is because the practical dosage of *x*-ray, at least in our hands, is more accurately controlled, than that of radium. This point seems to us, rather an important one in the therapeutic comparison.

In our section of the country, we see quite a bit of lupus-erythematosus. It was found that radium therapy gave much better results than Roentgen ray in this disease. Most of the indicated cases were treated at the same time with gold sodium thiosulphate. We feel that results were much better in those lesions to which radium was applied. I think that in the past, many cases of lupus-erythematosus were treated by too strongly inflammatory methods. It was found that where the dosage of radium was fractional and an effort made to avoid an acute reaction that a much better result was obtained. Without attempting here to discuss Alpha, Beta and Gamma rays, it was found that filtering the radium in the range from a rubber dam up to a millimeter of aluminum according to the induration of the lesion, was most effacacious. The extent of the eruption, general acute sensitivity and reaction, number and location of the lesions, amount of the scaling and the induration, and even the general constitution of the patient, are all important factors in influencing the dosage of radium therapy. It requires skillful management to obtain good results in using radium for lupus-erythematosus. While we are impressed with the usual proportion of good results which gold sodium thiosulphate produces in lupus-erythematosus, we feel that mild radium therapy is usually a very advantageous addition to treatment. It might be stated that where gold sodium thiosulphate is used, radiant therapy of any kind should be given in small doses. We have practically given up the use of the Kromayer lamp pressure treatment, and carbon-dioxide snow, in treating lupus-erythematosus.

We thought that lupus-vulgaris, treated with fractional doses of radium responded better than it did to *x*-ray. Most of the lupus cases were comparatively early, and not of great extent, but they always seemed to respond well to radium. In other tubercular lesions of the skin, the Roentgen ray appeared to be as efficacious as radium, and was usually employed. When the tubercular lesion was associated with a purulent discharge, we always added ultra-violet ray to our treatment. In such cases, especially those with sinus formation, we felt that ultra-violet ray was an effective aid. We preferred radium in treating various types of onychia and paronychia. Some of the infected, deep, persistent cysts of acne were shielded off well and treated with filtered radium. The chalazion cysts of the eyelid, when the capsule was not too old and thickened, responded perfectly to radium in a great many instances. The obstinate cases were removed by electrolysis. It was not found necessary to use the knife in any case. When these cystic lesions are multiple, radium or *x*-ray is the preferable treatment. It is surprising to find what small doses of radium or *x*-ray often effect the removal of the early chalazion. We preferred radium in treating some of the localized congestive or pernio lesions producing chronic swelling, such as occur at the tip of the nose. Granuloma pyogenicum, when it was not treated by electrolysis, responded better to radium than to *x*-ray. Small and superficial scars and keloids were treated with radium in preference to *x*-ray. Filtered *x*-ray was used in treating extensive keloids. The heavier and deeper the lesion the more filtration of radiant therapy was employed. Extensive and long standing keloids require more of the proportion of the more penetrating ray. The treatment of scars in industrial work, with radium and *x*-ray, has produced good clinical results and we find that more and more the compensation insurance companies are appreciating the results obtained by this form of treatment. We used filtered *x*-ray to advantage in treating cases of chronic lymphangitis, especially those associated with long standing and persistent angioneurotic edema. This type of lesion about the face is quite unsightly and annoying, and we wish to recommend filtered *x*-ray or radium to give slow, but decisively improving results. Radium was of course, used in treating the vascular, keratotic and other similar lesions of *x*-ray burn.

Most of our *x*-ray work was done with a spark gap of from six to eight inches. We did not find that using softer rays improved our clinical results. We have had no experience in treatment with the so-called Grenz rays. For the past several years almost all of the dermatologists have been reporting their observations on treating the lesions of the skin with *x*-ray and radium. After all, as McKee points out in his wonderful book, there is little difference in the action of Roentgen ray and of radium. But in comparing therapeutically, Roentgen ray, and ultra-violet ray, we are dealing with quite differently acting agents.

When the dermatologist uses ultra-violet ray he ought to use that from a mercury quartz burner. For purposes of treating the skin, at least, we feel that the day of the carbon arc lamp either has gone or has not yet arrived. Much of our work with ultra-violet ray has been done in combination with treatment by Roentgen ray. We did not find that exposure to ultra-violet ray enhanced the possibility of causing an *x*-ray or radium dermatitis, or later atrophy. Of course, we did not attempt to put an erythema dose of *x*-ray on top of an ultra-violet ray reaction.

Ultra-violet ray, as we use it in practice, has the following qualities: It is chemically active, has some action on metabolism especially in chil-

dren, produces erythema, vesiculation and desquamation, and thus is a superficial stimulant, and it kills micro organisms of the bacterial variety on the cutaneous surface Its action in treating cutaneous disease is necessarily a superficial one It does not inhibit sebaceous secretion does not penetrate the vascular layers of the skin does not inhibit sweat gland activity and does not cause atrophy It does not cause epilation and in general produces no lasting harm It ought to be mentioned that there rarely are individuals whose skin is very sensitive to sunlight and in whom it is possible to have permanent atrophic lesions follow severe sunburn However, the fact remains that it is a much safer ray to use than *x*-ray Somewhat paradoxically it might be said that *x*-ray tends to relieve inflammation of the skin and ultra violet tends to produce it We find that our results in combining treatment of Roentgen and ultra-violet ray were especially worth while in the following diseases of the skin Seborrhœic eczema and seborrhœa of the scalp, psoriasis, acne, impetigo, rosacea, infectious eczematoid dermatitis, acne varioliformis and tuberculides, onychia and paronychia, lichen planus, lupus vulgaris and other tubercular lesions, dermatitis papillaris capillitii, furuncle and carbuncle In seborrhœic eczema of the scalp we use preliminary *x*-ray to relieve itching, oozing, and inflammation and yet not produce epilation, later using ultra-violet ray as a stimulant with a certain amount of parasiticidal action We believe that recurrences in these seborrhœic conditions are much less annoying when ultra violet ray is used Where the hair is heavy, the action of ultra-violet ray is often not sufficiently received by the scalp *X*-ray quickly relieves the unsightly lesions at the hair line border in psoriasis of the scalp as well as the heavy psoriatic patches After one or two treatments, we discontinue *x*-ray and use ultra-violet ray Pressure treatments with the Kromayer lamp directly to a patch of scalp psoriasis is quite effective In treating psoriasis of the body it is now quite well known that while at first Roentgen ray is efficacious, sooner or later the lesions develop an immunity and no longer disappear For this reason we "save" *x*-ray to use when lesions appear on places exposed to public view It is also wise to "save" *x*-ray for treating the inflamed patches of psoriasis occurring in intertriginous areas, such as the umbilicus, groin, and natal cleft Unless the patient can be frequently exposed to the ultra violet ray to the point of producing a general tanning we have found its action disappointing, in many cases I think outdoor exercise in bright sunshine the most efficacious, even if impractical, method of dealing with psoriasis

When impetigo is inflamed and associated with more or less dermatitis, a preliminary treatment with an eighth to a quarter skin unit of unfiltered *x*-ray is quite effective This soothes the inflamed areas, lessens discharge and makes for less extension of the infectious process We begin at once local treatment with two to three per cent ammoniated mercury ointment In about twenty-four hours we apply a moderate erythema dose of ultra violet ray and repeat this when we think necessary The simple case of impetigo will respond very well to ultra violet ray alone Infectious eczematoid dermatitis and the infectious seborrhœic eczemas occurring about the pinna of the ear respond much better to *x*-ray than to ultra-violet light The dose of *x*-ray in these conditions must be quite light After the inflammation subsides we like to continue ultra-violet ray in doses just under an erythema We treat the fibrous scarring and inflammatory elements of dermatitis papillaris capillitii, cicatricial alopecia and acne varioliformis with *x*-ray, and then continue with ultra violet ray as a stimulant and to take care of the pyogenic infection We feel that in these three diseases it is quite necessary to use this combined treatment

In treating rosacea we of course pay attention to gastro intestinal and other possible reflex vasomotor causes We treat the vascular manifestations of rosacea with mild doses of *x*-ray, using only about one eighth unit of unfiltered ray at two week intervals We then begin ultra violet ray in a dosage enough to produce the slightest erythema This takes care of the pustular element of rosacea and we feel that it also has a stabilizing action in combating local circulatory disturbance We occasionally give further *x* ray treatment to the rhinophyma stage but here we use filtered *x*-ray or radium instead of the unfiltered This combined treatment is very effective in rosacea It might be mentioned here that we prefer unfiltered *x* ray and radium in treating superficial inflammations of the skin but employ filtered ray in deep lesions where fibrous changes are occurring

The itching of lichen planus is best relieved by *x* ray but early acute generalized lichen planus responds very well to an erythema dose of ultra-violet The writer has taken cases of generalized lichen planus in the first week or two and has cleared them entirely with ultra-violet ray alone Of course the lesions under this treatment quickly recur unless internal treatment is begun at once We always use mercury or arsenic or both in our lichen planus cases The more indurated lesions of lichen planus respond better to *x* ray than to ultra violet This is even more true of hypertrophic lichen planus But there finally comes a time when the use of *x*-ray should be dispensed with and here ultra violet ray is certainly a great aid In such chronic cases, we have cleared up some heavy hypertrophic lichen planus lesions with mild pressure ultra violet therapy

We have been much impressed with the results

obtained in treating acne vulgaris of all kinds with a combination of Roentgen and ultra-violet ray. We begin by using *x*-ray to check the seborrhœic activity. After a few treatments the ultra-violet ray is used at regular intervals in a dose to produce erythema followed by desquamation. We try to avoid vesiculation and bleb formation in treating any disease of the skin, with ultra-violet ray. The ultra-violet ray has a marked action in reducing the infective process and its desquamating action is also quite valuable. At intervals of a month or so we interject an *x*-ray treatment of one-quarter unit of unfiltered *x*-ray. Except in acne of the back with keloidal scarring, not many *x*-ray treatments are required. Along with the radiant therapy we employ the usual mild sulphur lotions, almost always lotio alba. In cases where there is much pus formation we may employ vaccine. One of the troubles in treating acne is that the physician is inclined to apply only one remedy. One uses local applications alone, another *x*-ray alone, another ultra-violet ray alone, and quite often vaccine alone is given a trial. The pathology and etiology of the disease require that all these methods of treatment should be used. We have found no reason not to combine them. We keep our *x*-ray and ultra-violet ray treatments at least a week apart. This combined treatment makes it possible to employ less *x*-ray and this is a good thing for the skin. We also are not troubled with the patient who is pleading for a continuation of the *x*-ray treatment that at first brought about so much relief but which might later on cause so much harm.

In general we did not find that ultra-violet ray helped very much in taking care of eczema. We did not like it on the acutely inflamed skin. It was as a rule quite a disappointment in treating the many kinds of fungous dermatitis. We think that the acute generalized cases of this disorder are usually made worse by treatment with ultra-violet ray. The pompholyx type of ringworm of the palms and soles respond poorly to ultra-violet ray except in cases where the staphylococcus complication was prominent. Some of the chronic types of ringworm eczema of the hands, especially on the dorsal surface, responded quite well to ultra-violet ray when the surface became tanned. Of course where continued stimulation of an area was desirable by radiant therapy it was necessary to use ultra-violet. We believe there is much to be gained by treating furunculosis and carbuncle with *x*-ray and ultra-violet. *X*-ray has a valuable action in treating infections of the hair follicles, and the counter-irritating and superficial parasiticidal action of ultra-violet ray is also an aid. We treated large furuncules and carbuncles by using quite heavy doses of filtered *x*-ray. Often this caused a resolution of the lesions without draining. When drainage occurs we like to add the poulticing action of ultra-violet. With the proper applicator, the Kromayer lamp may be effectively used to treat furunculosis of the ear canal. Quite a bit has been claimed for the ultra-violet ray in treating varicose ulcers. This proved a poor treatment in our hands. We did find the *x*-ray of use in treating the eczema associated with varicose ulcer. We felt that radium and other measures were superior to the Kromayer pressure treatment in dealing with nevus. The thickened nail of ringworm and other onychias was occasionally treated with *x*-ray or radium and in the intervals ultra-violet ray used as a stimulant and to combat the staphylococcic paronychia. There are really very few conditions where ultra-violet ray alone is a therapeutic sufficiency. We stimulate the bald areas of alopecia areata with ultra-violet ray and feel that it is a satisfactory treatment in certain instances. However, this is one of the fields in which ultra-violet ray has been abused with much quackery, not only in the realm of medicine but by the public in general. We have tried the ultra-violet ray in several instances where atrophy of the skin was feared or had begun as a result of the Trico method of treating superfluous hair. We have not had enough cases nor a sufficient length of time to draw conclusions but feel there is a certain amount of promise in this endeavor. The treatment of *x*-ray telangiectasia and atrophy by the use of the Kromayer or the air lamp did not give good results in our hands. While ultra-violet ray is now quite generally used and is relatively harmless it is quite as necessary to adopt an accurate technic with it as with *x*-ray. The haphazard "lamp" treatment used both in cases where ultra-violet ray is indicated, and where not indicated, has harmed our general therapeutic efficiency more than tongue can tell. It has now come to the point where the public is dabbling in the treatment of about every known disease with some lamp or other. The mercury quartz burners were too expensive to sell to the public in quantity so manufacturers have devised lamps which sell in drug stores from $10 up. Some of these lamps produce no practical ultra-violet ray at all, but are graced with the advertisement of producing a ray honored with the name infra-red. Sometimes the busy physician seems to forget that the therapeutic efficiency of infra-red rays is no more than that of giving off heat.

So sorely are we in need of real cures in our profession that we are inclined to rely too much on treatments which give bright promise but sooner or later fade out of the picture. We should be rather cautious and take plenty of time to evaluate the results obtained where the more newly discovered light rays are used in therapeutics. However, progress will continue and experimentation lead to ultimate benefit in treating the ills to which the flesh is heir.

BACTERIOPHAGE. ITS APPLICATION IN DERMATOLOGICAL PRACTICE

By ANTHONY C. CIPOLLARO, M.D., NEW YORK, N. Y.

From the Departments of Dermatology and Syphilology and Laboratories of the New York Post Graduate Medical School and Hospital
Read before the Dermatological Society of the New York Post Graduate Medical School, November 13, 1930

THE phenomenon of bacteriophagy was first observed by Twort (1) in 1915. Upon observing the death of bacteria in some of his cultures, he was led to believe that his bacteria were attacked by a plague wiping out colonies of bacteria.

D'Herelle (2) studied this phenomenon most persistently and exhaustively. He applied this principle to clinical medicine and gave to humanity a most powerful weapon with which to combat effectively devastating diseases. This author observed that when the stool obtained from a patient suffering with bacillary dysentery was filtered, and the filtrate applied to a culture of the stool, the colonies of bacteria were wiped out, dissolved, lyzed, disappeared and nothing remained visible where these bacteria formerly were. This is the principle of bacteriophagy. D'Herelle expanded this piece of research and included in his studies most of the known pathogenic organisms.

Mode of Preparation

The most abundant sources of bacteriophage are sewage and stools. A series of broth cultures of different organisms is set up, and to each tube is added some sewage or stool filtrate, and incubated. Clearing of the broth cultures is evidence that the organisms have been attacked by their homologous bacteriophages. These form stock bacteriophages. This process is carried on using materials from different sources until all known races of bacteriophage have been obtained. This is the trial and error method of equipping the laboratory with different races of bacteriophage. A simpler way is to obtain races of bacteriophage from those laboratories which are already supplied.

In the treatment of a patient with bacteriophage, it is essential in every case to test the susceptibility of the organisms to the bacteriophage to be used. This is done by taking a culture from the lesion to be treated, and growing the organisms for 24 hours to determine their nature and susceptibility. Add to this broth culture some of the bacteriophage, incubate, examine every 6 hours and notice if lysis takes place. If the broth clears in 6 hours and stays clear, we have a very potent bacteriophage. If lysis takes longer, then the bacteriophage is less potent. We take this broth culture that has been lyzed by the specific bacteriophage and filter through a Chamberland filter. The filtrate is an autogenous bacteriophage. It matters not whether the autogenous or stock bacteriophage is used, just so long as we get lysis.

Properties of Bacteriophage

The nature of bacteriophage can be concisely and briefly presented by making a numerical list of its properties.

1. Bacteriophage is lytic. It kills and dissolves bacteria in large numbers, and it has been estimated to be potent in dilution as great as 1/100,000,000.
2. Alcohol renders bacteriophage inactive.
3. It permeates tissues.
4. It is innocuous. It does not injure cells.
5. Repeated inoculations may produce anti-bacteriophage antibodies, and may lead to increased susceptibility to infection by the homologus bacteria.
6. It stimulates macrophage production thereby increasing phagocytosis. These phagocytes act on bacteria so as to make them more readily and rapidly digestible. It also stimulates the leucocytes to greater phagocytic activity.
7. Bacteriophage lyzed cultures are antigenic because of the proteolysis of the bacteria lyzed. The protein content of bacteria makes good antigenic material. It is the bacterial protein in a vaccine that makes it valuable. Hence, bacteriophage may be considered to be a supervaccine.
8. It multiplies on artificial media as well as in vivo.
9. In destroying colonies of bacteria on petrie dishes it acts much like a living thing and not like a chemical enzyme.
10. It is transmissible.
11. Bacteriophage attacks young actively growing bacteria more readily than older bacteria.
12. The more acute the infection, the more efficacious the bacteriophage.
13. Bacteriophage produces antibodies, the same as dead, living, or autolyzed bacteria; but the antibodies produced by bacteriophage are developed more rapidly and protect better than bacterial antibodies.
14. It is said that it is just as efficacious in influencing the course of a disease, whether the bacteriophage is applied at the site of the lesion, or subcutaneously at a distance from the focus of infection.
15. The lytic principle is a living, filtrable, ultra-microscopic organism (virus), which is parasitizing and rapidly multiplying at the expense of young rapidly growing bacteria.
16. It is specific in its action.
17. Some of the miscellaneous properties which have been ascribed to bacteriophage and which have not been accepted by all workers are the following:

a. The lytic principle is volatile.

b. The action of the lytic principle is due to the autolytic changes in the bacteria themselves.

c. Bacteriophage activates the normal proferment existing in bacterial cells.

d. The action of bacteriophage is due to the effect of transmissible degenerative changes in bacterial chromosomes.

e. Bacteriophage is in the nature of a receptor, etc.

Elaboration of these properties cannot be undertaken at this time as the field is too large.

Clinical Application in Acute and Chronic Diseases

My interest in bacteriophage was aroused because of the inadequate methods we have at our disposal in the treatment of sycosis vulgaris. Some severe cases of radiodermatitis from the use of X-rays in treating this condition have come to my attention. I have been moved by these sequelæ to find some method that would cure the disease permanently and not injure the skin. In the entire field of therapeutics, bacteriophage holds out the greatest hope.

While carrying out this study, I have also placed considerable emphasis on those conditions that are curable only with considerable expense of time and money. The diseases that have held my interest are: staphylococcic abscesses, staphylococcic infected cysts, carbunculosis, furunculosis, acne vulgaris (pustular type), chronic staphylococcic pyoderma, impetigo contagiosa, etc.

While I admit that in general incision and drainage is the method of choice in treating lesions where there is encapsulated pus, yet there are locations such as in the nose, on the upper lip, cheek, etc., where surgical intervention may lead to serious consequences. Sometimes surgical intervention of pyogenic infection in these locations is directly responsible for sinus, thrombosis, meningitis and in some cases death. Bacteriophage in this type of infection finds its usefulness great.

Carbuncles respond remarkably well when a potent bacteriophage is used. As little as twenty-four hours after the administration of bacteriophage, one can see how the thick purulent material and the slough become thin and liquid. Pain, malaise and toxemia are much ameliorated. There is a feeling of remarkable well being. After resolution there is little scarring; ever so much less than when these lesions are treated by incision and drainage.

The type of furunculosis I have been particularly interested in, is the type that recurs and appears in crops and persists for long periods of time. In these cases it has been my object to immunize the patients against this disease. Years of observation on thousands of cases will tell us how efficacious this agent is in rendering lasting immunity in recurrent furunculosis.

The few cases of impetigo contagiosa that I have treated, have all been cured within one week by the local and subcutaneous administration of bacteriophage. Ammoniated mercury ointment might have done as well in these cases, yet bacteriophage may be of great value when this disease assumes a bullous form in the newborn where it is often fatal. Wet dressings of bacteriophage and its subcutaneous administration may save many lives.

Acne vulgaris and infected acne cysts have not responded as favorably as other conditions which I have treated with bacteriophage. This failure to respond is now being studied both in the laboratory and in the clinic.

The Technique of the Application of Bacteriophage

Certain investigators notably Gratia (3). D'Herelle (2), Arnold and Weiss (4), etc., have claimed and proved experimentally on laboratory animals, that bacteriophage is just as efficacious when injected subcutaneously at a site distant from the pathology as when applied locally to the lesion. Among those to stress this point I might mention Walker (5). The experiment which he performed was the following: The author injected B. coli into the peritoneal cavity of two series of 6 mice each. At the same time, bacteriophage was injected subcutaneously on the back of one series of 6 mice. Four mice out of the 6 protected with bacteriophage survived, while only one mouse out of the six not protected with bacteriophage survived.

There is no unanimity of opinion as to the method and site of application of bacteriophage. There is no disputing the fact that if subcutaneous injections of bacteriophage at a site distant from the pathology is good, then application of the bacteriophage at the site of pathology is better. Many clinical workers have had this same experience.

My first cases were treated routinely by subcutaneous injections with indifferent and poor results. As a result of reading the literature, it occurred to me to inject bacteriophage subcutaneously as well as apply it directly to the lesion. The results of this method have been gratifying. The method of application depends upon the nature of the lesions. In a solitary furuncular lesion or carbuncle or abscess, the bacteriophage is injected into the lesion. In a case of sycosis vulgaris, pyoderma, impetigo contagiosa and widespread infections, the bacteriophage is either swabbed on or applied as wet dressings. Bacteriophage may be ingested or given intravenously. The number and frequency of treatments depend upon the clinical course. It is advisable to administer bacteriophage at intervals no longer than 48 hours.

To make this concrete, let us take a case of sycosis vulgaris. A few hairs from the infected area are removed and a culture made. The organisms are tested for susceptibility to bacteriophage. If the bacteriophage is potent, it is to be injected subcutaneously into the arm in 1cc doses daily up to 30 injections. At the same time the bacteriophage is swabbed on the lesion. This is done daily. If improvement is slow, bacteriophage may be applied in the form of wet dressings.

If we are treating a case of furunculosis, then the bacteriophage is injected daily into the lesion until its disappearance, and using from ¼ to ½ cc. Bacteriophage is also administered daily subcutaneously in 1cc or 2cc doses, depending upon the duration of the treatment. If a single furuncular lesion is being treated, 3 or 4 treatments will usually suffice, and for a short course it is advisable to use 2cc at each injection. If the case is one of recurrent furunculosis of long duration, then it is best to give 30 injections of 1cc each, with the hope of increasing the local resistance.

I am aware of the possibility of the formation of antibacteriophage antibodies. D'Herelle and others have made the claim that repeated administration of bacteriophage makes the individual more susceptible to the infection. But my clinical experience, and that of Crutchfield and Stout (6), does not bear out this point. We have cases to show which did not respond to a few injections, but did respond to many injections. Arnold and Weiss (4) showed experimentally that increased dosage of bacteriophage does not make the laboratory animals hypersusceptible to the homologous bacteria.

The results from bacteriophage therapy may be predicted in many cases. The prediction is to be based on two main factors; first the ability of the bacteriophage to lyze the organism and second the potency of the bacteriophage. If we meet with failure, it will be due to the fact that the etiological agent has changed, and is no longer susceptible to the bacteriophage we are using. We must always bear in mind that with bacteriophagy there is a certain specificity. It will lyze only certain organisms, and if in the course of time, the causative agent which is lyzable is superceded by another agent which is not lyzable by the bacteriophage administered, then the bacteriophage will fail to produce a cure. If we are treating a staphylococcic infection and a streptococcus steps in, our staphylococcic bacteriophage may be absolutely useless against the streptococcic infection. A given bacteriophage may parasitize on bacteria belonging to different species and yet may not destroy all strains of the same bacteria for which it is most potent. Many failures recorded are due to two reasons; first to the failure of the bacteriophage to lyze the organism, and second to the changing of the etiological agent. In other words the proper bacteriophage was not used. A specific bacteriophage must be used for its homologous organism. The term specific is used in relation to bacteriophagy to stress the importance that any bacteriophage may not be used for any infection. A potent polyvalent staphylococcic bacteriophage may not necessarily lyze all the strains of staphylococci, and yet this may possibly lyze an organism totally unrelated to staphylococci. In all cases, a test for susceptibility should be done to determine the potency of bacteriophage.

Reactions following the administration of bacteriophage are few and are of little consequence. These reactions are local in nature and limited to the area inoculated. Systemic reactions have not been noted from the use of bacteriophage. Sterility must be very strictly adhered to. Nonpathogenic air borne organisms may be introduced into rubber stoppered vials if needles and syringes are left exposed to the air for prolonged periods after sterilization. Only freshly boiled needles should be introduced into the vials. The vials used should be of transparent glass, so as to be able to see if contaminating organisms have been introduced. Some severe local and systemic reactions can be traced to the introduction of nonpathogenic air borne bacilli into vessels containing bacteriophage at the time of its administration. It is my opinion that by a careful technique, all systemic reactions may be avoided, unless a patient is allergic to bacterial proteins, or to products in the vehicle.

The report on a series of approximately one hundred cases of pyodermata is now in preparation and will appear in a later paper.

I wish to acknowledge my thanks to the Macy Foundation, Drs. MacNeal and Sheplar of the department of laboratories, and Dr. MacKee of the dermatological department, for their active cooperation and helpful suggestions. Without their aid this paper could not have been written.

IMPORTANT ASPECTS OF MEASLES*

By PHILIP M. STIMSON, M.D., NEW YORK, N. Y.

IN presenting certain aspects of measles, this paper will stress the following points:

1st, The priority of fever in the symptomatology of the disease.

2nd, The importance of eye signs in the early diagnosis, and

3rd, The necessity for the rigid individual isolation of measles patients. To tie these subjects together, there will be presented a procedure, or course of action, should a family be exposed to measles.

Let us imagine a family of children aged eight, six, five, and two, and an infant of four months. The third child, five years old, has broken out with a measles rash beginning on the 4th of the month. Therefore, the first day of the month must be considered the first day of exposure for the others, measles being definitely contagious for at least three days before the appearance of the exanthem. The other four children have all been markedly exposed to the disease, having been attended to by the same mother or nurse. What shall be the procedure?

The Infant: First, the infant of four months. The mother has had measles. It is therefore reasonably safe to assume that the baby has still an inherited immunity, enough either to give him complete protection, or to protect him sufficiently so that he will not have more than a modified form of the disease, from which he will have little trouble recovering. And Herrman has shown that if four months old babies are exposed to measles it is possible that, without contracting the disease, they may nevertheless be sufficiently immunized to give complete protection against future exposures.

The Two-Year-Old: The two-year-old child in this family is none too robust. Yet he is at a most susceptible age. He needs help. Accordingly he receives intramuscularly 4 to 6 c.c. of blood serum from a recently convalescent patient, if any such serum is available; otherwise 10 to 15 c.c. of the serum, or twice as much of whole blood, from one of his parents. In this case, one will hope either for a complete though temporary immunization, or for a very mild or modified case of the disease, but one which will nevertheless be enough to give him immunity for life.

About the fifteenth or sixteenth day he perhaps does develop the fever of modified measles, which runs up to about 101 at its highest and lasts only three or four days. He has a mild diffuse macular rash irregularly scattered over his face and body and a very slight catarrh, but no Koplik's spots, and practically no conjunctivitis—in fact, no means by which a diagnosis of measles can be made except his history of exposure and of having received serum. However, he has probably developed an immunity to measles for life.

The Older Children: The eight and six-year-old girls may either be given parental blood as was perhaps done for the two-year-old child, or they may be allowed to take their chances since they are thoroughly fit. They may not have convalescent serum, because, being scarce, it is all needed for other children who are greater risks. Since fever is almost invariably the first evidence of the disease and the incubation period is seven to fourteen days, their temperatures shall be taken four times a day beginning on the eighth day, instructions being given to put a child to bed with the onset of fever and to isolate her. This may save the other child from a re-exposure. However, probably before the eleventh or twelfth day, one or both will show a definite fever, the one having perhaps only a degree, the other even as much as 102 on the first day of fever. This latter, the six-year-old, may have nearly normal temperature on her second day, her fever then rising again and rapidly—a malarial form of fever curve. Many of the measles cases this spring have been of this latter type, and for two or three days have much resembled grippe. Even Koplik's spots have seemed slow to appear. The former child, the eight-year-old, proceeds to have more and more fever each day for three or four days, or five, until her rash comes well out. Yet it is undesirable to wait for the rash to give certainty of diagnosis, or even for the buccal spots of Koplik, for it must be borne in mind that it is the early catarrh that is most apt to spread the disease, and that this catarrh is usually present one to two days before Koplik's spots are found. Therefore the children's eyes must be watched.

The Measles Line: In the eight-year-old, ere the fever is 24 hours old, if the lower eyelid is pulled down a reddish streak or line is noted already present, the so-called *measles line,* parallel to the lid margin. By the next day it has already become a band involving most of the lower lid, and the caruncle at the inner corner of the eye is slightly red and swollen. This measles line, first reported in November, 1927, has now been seen by a number of observers. I have personally noted it in some thirteen cases, have failed to find it when I thought it should be present in two or three other cases, and in two instances two years ago have thought it present in patients which subsequently proved not to have measles but grippe, a disease wherein the lower lid is often also congested though usually rather more diffusely from the start.

* Read before the New York County Medical Society, May, 1928.

Red Macule In addition to this measles line the six-year old on her second day of fever shows in one eye a small reddened macule on the plica semilunaris, and a day later a tiny white speck is found on its center—much like a buccal spot of Koplik Koplik's spots in the eyes have been reported by several observers, usually being seen as two or three whitish specks on the much swollen and inflamed caruncle found at the height of the disease But in three instances I have seen on the second day of the fever a definite macule on the somewhat swollen plica semilunaris with a suggestion of a streak of inflammation running in towards a caruncle which had just begun to become red and swollen So in this six-year old, that macule on the plica gives confidence in the provisional diagnosis that it is measles in this child and not grippe For when a youngster has fever and a linear conjunctival congestion, or measles line, measles should be considered, and if a macule appears on the plica and the caruncle becomes red and swollen measles becomes almost a certainty Of course, for further proof one looks for cough, coryza photophobia, a speckled injection of the tonsils and soft palate, and particularly for Koplik's spots

Koplik's Spots In this girl, on her second or third day of fever, one perhaps finds a little irregular reddening inside her cheeks But by artificial light it is difficult to be sure there are Koplik's spots present, and it is necessary either to take the child to a window or to wait until morning for more to appear And with the finding of these spots in the cheeks, of course the diagnosis is confirmed But it has paid to watch the eyes For here may be found signs which even when there is no history of exposure to measles, may enable one to suspect its presence in time to isolate the patient before much exposure of others has occurred

Isolation of Cases The girls have been put to bed with their onset of fever, even though the eight-year old with an elevation of only one degree protested that she felt fine The reasons for this action are these First any child with a fever should be in bed Second, the course of measles is usually milder if the patient is put to bed at the very onset Third, a case of measles in bed is of less danger to others than one up and about And fourth, perhaps the most important reason of all, a child in bed will be less apt to pick up a secondary infection

In fact these patients are not put to bed in the same room, but are scattered in the home as widely as may be It cannot be repeated too often that in measles it is the complications due to secondary infections that kill or cripple, and that these secondarily invading infections are nearly if not quite as readily spread from child to child as is the primary measles And the germ which may cause only a head cold or mild grippe in one child, or in a nurse, may cause otitis media and mastoiditis, or broncho pneumonia, in a measles patient Two other families out of many available will illustrate this point A professor's daughter developed measles The two small brothers had been markedly exposed The sick girl was isolated at one end of the apartment and was cared for by her mother, while a grandmother took sole charge of the boys at the other end of the apartment The girl developed a very severe bilateral otitis media and pyelitis, and was sick several weeks The brothers developed fever on the ninth and tenth days from first exposure respectively, were promptly put to bed in separate rooms and had uneventful cases without much discomfort and without complications The secondary infection was here kept isolated with the girl

The other family also had three children but lived in a miserably small apartment The oldest child started the trouble with measles, and then developed a running ear just at the time when the other two children in an adjoining bed were first breaking out In the next few days these three children had among them five running ears, three mastoid operations and a case of broncho pneumonia The secondary infection made far more trouble in that family than did the primary measles For there was absolutely no individual isolation there

So in conclusion, the following points are emphasized In watching for secondary cases of measles, one should expect to find fever as the first evidence of ill health Then the mucous membrane of the lower eyelids the caruncle, and the plica semilunaris should be carefully observed especially during the early prodromal period for at that time and in those places much helpful evidence of oncoming measles may be found And above all, every measles patient should be isolated from every other sick person, with measles or otherwise, but particularly from those with upper respiratory catarrhal infections, lest through neglect of this simple precaution the child add to his measles some secondary infection that may either cripple, as with impaired hearing —or even kill

DISTRIBUTION OF MEDICAL SERVICE

The Wicks-Hutchinson public health bill, embodying the suggestions of the Governor's special health commission, deals with the distribution of medical service. The Commission recognizes that the medical army is well trained and equipped to take the field against the forces of death and disease. The bill specifies what the people shall do in cooperation with the medical army, especially in providing it with hospitals and clinics, and in outlining methods of administration, so that the people themselves shall bear their just share of the burden of giving adequate medical service and health defense to every person regardless of his status financially.

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—NO. 18

The public health bill introduced by Senator Wicks and Assemblyman Hutchinson in the Legislature, for the promotion of public health, has aroused more public interest and as much medical discussion as any other legislative measure this year. The bill is the result of the study of the Governor's Special Health Commission of the adequacy of the existing health laws, the health problems of the present, and the administration of public health in the State.

The health problems of the State can be mainly met by effective health departments with qualified personnel, more facilities for the control of tuberculosis, cancer, and syphilis, better organization for the case finding and rehabilitation of crippled children, further coordination of school hygiene and health services,—all this involving an extension of public health nursing throughout the State so as to reach a standard now in effect in a few areas, additional safeguards in the purification of water, more attention to the growing problems of industrial hygiene, and improved organization for the preventive service in industry. The bill proposes the most advanced step in constructive public health development undertaken in years.

The Commission's proposals have apparently met with unanimous public approval. The entire press of the State appears to support the bill. Every large civic and social organization has endorsed it. Political leaders of the State have indicated their approval of the potential advancement of public welfare and public health that can flow from the provisions of the bill if enacted into law. The leaders of medical thought have complimented the Commission's report and have endorsed the bill. Most of the ex-presidents of the State Society have written letters of commendation and endorsement of the bill, stating that it is both in the interest of the medical profession and of the laity, and that enlightened public opinion generally supports the bill. Other States are becoming interested in the Commission's study. Within a week I have answered five requests from other States for copies of the Commission's report, the Governor's Health Message, and the bill, and two requests from State Societies to address them on the constructive public health development in New York State.

All this is a remarkable demonstration. It indicates more definitely than anything else that I have been able to observe this year, the public interest in better public health. Since speaking over the radio a few nights ago on the Commission's report many people have written me and the trend of thought is that the public is entitled to the service indicated in this bill. Some County Medical Societies are still considering their endorsement. Others have endorsed it.

The Erie County Medical Society has adopted a resolution by a vote of twenty-seven to seventeen out of a membership of eight hundred, stating that "the recommendations of the Special Health Commission are revolutionary and drastic and violate the principle of home rule and if enacted into law would confuse and disturb public health regulations * * * * * and result in chaos to the medical profession and to the public and would be inimical to the well being of our citizens." They have resolved to petition the Governor of the State to reconsider his special message to the Legislature in which he requested that the recommendations of the Special Health Commission be translated into legislation.

The resolutions are definitely expressed opinions and quite at variance with an editorial in the *Buffalo Times* of Wednesday, March 4, 1931. If this editorial is taken as an expression of public opinion, it is sufficiently informative to warrant perusal by anyone.

The State Sanitary Health Officers' Association objects to certain features in the bill. In conversation with the leaders of the Association, it seems that the major objection is that the bill does not make secure enough the tenure of office of the part-time health officers.

Let us realize that the bill proposes the most advanced step in constructive public health development in years. I hope that every physician will read the bill carefully. It proposes to enact into law the recommendations made by the Commission after a fact finding study for the last nine months by the Commission and its Sub-committees totalling eighty-six physicians and health experts.

Let us consider the salient features of the bill, first, the provision for organizing the public health work of the State with the county as the unit. The arguments in favor of this feature are so convincingly expressed in the report that it will be received with satisfaction, but there are certain details involved in the reorganization that may need some revision. Frank conferences between interested groups should result in ironing out differences of opinion. These conferences are now being held.

There are certain details, namely, the selection of a health board and a county commissioner, that each county should do very carefully and deliberately, not hastily. County Medical Societies will greatly aid the proper authorities in developing their preliminary plans so that no mistakes may occur in the reorganization. The bill intends a minimum amount of change in the present administrative personnel, and perhaps its wording can be improved for this purpose.

The next important feature is the provision for the construction and operation of three other tuberculosis hospitals by the State. Counties too

small to support a tuberculosis hospital of their own will now have adequate, accessible facilities. This will be a great boon especially to those counties who were obliged to go to distant counties to hire beds for their patients. These hospitals will also have great educational value to the medical men of their communities.

The third outstanding feature is the creation in the Department of Health of a division for cancer control. While knowledge of the cause and prevention of cancer is even more hazy than was the knowledge of tuberculosis when antituberculosis work was first undertaken as a public health problem, there is reason to believe that much can be accomplished by a State Department. The reduction of venereal diseases and the rehabilitation of handicapped children are given careful consideration and provision made for their advancement in their fields.

Of course, the first draft of this bill may not be entirely satisfactory in detail to everyone and amendments and revisions will have to be made before it is finally enacted into law. The principles, however, are so definitely and clearly stated that there can be no misunderstanding of their intent.

The recommendations of the Health Commission were arrived at after long consideration and they are intended to meet the present day health problems of New York State. In all this study medicine has been liberally represented. There has been presented the viewpoint of the practicing physician.

During the last three years the administration of organized medicine has stressed the importance of the relationships of medicine and the need of medicine's leadership in sound health programs. Medicine today is confronted and challenged by public opinion. Public opinion has caused government to take a different attitude toward the welfare of its people. The problems of hygiene in industry have increased and the present day social medical needs run with appalling swiftness. Public opinion challenges medicine today to increase the availability of the resources of scientific knowledge for the prevention of disease and the protection of child health. Irrespective of what has been done, there is still much to do.

There was statesmanship enough one hundred twenty-four years ago to foreshadow preventive medicine when the membership of the State Society was just seventeen people. There was statesmanship enough one hundred twenty years ago when social problems and public relations were discussed when the membership was twenty people. There was statesmanship enough in organized medicine eighty years ago to reorganize medical education. Is there statesmanship enough in medicine today to assume leadership in the solution of the great problems of health and sickness service distribution, with twelve thousand members?

Changing times demand a changing attitude of organized medicine. The science of medicine is secure but its medical relationships do not make the profession of medicine secure unless medicine makes it so. We need in medicine no less than in public life, a spirit that will not set private gain above common welfare or the common good.

No activity in history has ever pleased everyone. Willingness to sit down together will reach satisfactory compromises. Misunderstanding is usually based on the smaller things. The objectives are frequently found to be the same and differences only exist in methods. The criticisms of medicine must be met, increasing a little more rapidly than is healthy for the profession.

The subject of this comment — constructive health advance before the profession—is a matter of public policy. Action will in the end measure professionalism. The decision will reflect medicine's statesmanship. It will reveal medicine's capacity for leadership. It will show medicine's capacity to tackle the problems of health and sickness service already called America's greatest problem by both medical men and laymen.

WILLIAM H. ROSS.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Quack Legislation—The present attempts of cultists to get licenses to practice in New York State recalls an act which was described by Dr. James J. Walsh in the NEW YORK STATE JOURNAL OF MEDICINE of March, 1906, as follows:

"On February 28, 1806, a bill was passed granting to a certain John M. Crous, the sum of $1,000 for a cure for hydrophobia, which he was said to possess. Most of the legislators, however, were the descendants of the old Dutch burghers, and had a proper sense of economy about them. They were not quite so easy to fool as they seemed. They fastened a good string to their appropriation of $1,000, by requiring Mr. John Crous to file a bond before the Supreme Court of the State for $2,000, in order to make ample provision for the return of the $1,000 if, after the end of four years, it should prove that his remedy were deceptive. Of the further history of Crous and his remedy unfortunately there are no data at hand."

MEDICAL PROGRESS

Bismuth Oxychloride Ointment in the Treatment of Lupus Erythematosus—R M B MacKenna reports a series of 19 cases of lupus erythematosus in which bismuth oxychloride was employed with benefit in every instance Five of the patients were entirely cured by the use of the ointment in conjunction with injections of bismuth The ointment is the result of experiments carried out at the St Vincent Laboratories, Glasgow It contained at first 5 per cent colloidal bismuth oxychloride, which was later increased to 10 per cent In all of the cases the ointment was applied freely and rubbed with moderate vigor on the affected areas for at least two minutes twice daily In nearly all of the cases injections of bismuth or bismuth salts were given at fortnightly or monthly intervals in order to intensify the action of the ointment MacKenna is convinced, however, that the average patient with the disease can be cured by the persevering application of the ointment alone but the time in which a cure may be obtained can be shortened by giving a few injections of one of the usual bismuth preparations The ointment appears to have a slight antiseptic or bactericidal effect It has also been employed with advantage in two cases of tinea unguium and in two cases diagnosed as chancroid An attempt was made to determine whether or not colloidal bismuth oxychloride in ointment was absorbed by the skin in sufficient quantities to make bismuth injection a feasible proposition in syphilis The results indicate that, while the preparation may be of some value as a local application, it is valueless if used as an injection—*The Lancet*, January 17, 1931, ccxx, 5603

Diuresis through Conditioned Reflex—In the *Klinische Wochenschrift* of January 10, 1931, Hellmut Marx describes his experiments on dogs in which he undertook to discover whether it is possible to produce diuresis in animals by means of psychic influence Four dogs of about equal weight but of different breeds and temperaments were kept under the conditions of a metabolic experiment from February 1929, to March, 1930 They received a standard diet and a constant fluid intake always at given times in the day Every day except Sunday they were catheterized in the morning, placed in a special room and chained up After they were quiet and lay still in their places, a musical signal was given on a harmonica and a pan containing 400 c c mixed milk and water 1 2 set before each While they drank the signal was given again 4 times, directed to each dog Then they were left quietly at rest for 3 hours, after which each was catheterized again and brought back into the metabolic cage Amount and specific gravity of the urine obtained was recorded After establishing this habit for 6 weeks, the dogs were once or twice a week brought fasting into the room and given only an empty dish with nothing to drink, with the usual musical note, after which they had the usual rest and catheterization It was hoped that under the usual drinking conditions a reflex would have been formed which would result in diuresis For 5 months nothing happened Then a 3 weeks' vacation broke the experiment and it was feared the effect of the long training had been lost The reverse was the case On the third day of the resumed experiment and the first day of faked drinking, one dog exhibited a veritable diuresis of 180 c c urine with a specific gravity of 1 007 It was thus judged that this was a case of diuresis through conditioned reflex, in view of the fact that the amounts of urine on drinking days had been in 3 hours 145 205 c c and the specific gravity 1 007-1 010 The experiments show that in the animal diuresis can be produced by the psychic route They therefore offer a new proof of the significance of cerebral regulation for diuresis The method seems a useful one for studying certain psychic mechanisms in the animal, since it was here possible for the first time to make quantitative estimates of the intensity of the effect produced

The Differential Diagnosis of Subacute Bacterial Heart Disease—William D Reid cites a case which serves to illustrate the importance of distinguishing between subacute bacterial heart disease and Banti's disease In the latter affections splenectomy is indicated while it is unwarranted in *Streptococcus viridans* infection In Reid's case too much attention was given to the enlarged spleen and anemia and too little to the petechiae chills detailed of the blood fever, history of probable embolism etc Splenectomy performed for supposed Banti's disease was without benefit The patient died from cerebral hemorrhage and the autopsy showed a definite *Streptococcus viridans* endocarditis In Banti's disease the blood usually shows a low color index, leucopenia and frequently changes in the ery

throcytes. In subacute bacterial heart disease the white blood count may vary from 20,000 or higher to 6,000, it being not uncommon to find a difference of many thousand within a few hours. The presence of large phagocytes is certain evidence of subacute bacterial heart disease. The finding of one or two large mononuclear cells with an ingested red cell or an increase in the number of large mononuclear cells is evidence of *Streptococcus viridans* infection. In Banti's disease the temperature is usually normal or there is slight fever from time to time, while in subacute bacterial disease there is fever of the septic type. Petechiae occur in about half the cases of *Streptococcus viridans* infection, while they are not mentioned by Stevens in connection with Banti's disease. Clubbing of the fingers and toes occurs in 70 per cent. of the cases of subacute bacterial heart disease. In this condition the spleen is usually only moderately enlarged, though in the case reported it was markedly enlarged; in Banti's disease it is grossly enlarged. Ascites, bleeding, usually from the esophagus, and hepatic cirrhosis, often present in Banti's disease, are not found in subacute bacterial heart disease. Chills and sweats are common in *Streptococcus viridans* infection, but not in Banti's disease. Heart murmurs are more frequent in subacute bacterial heart disease, and the *Streptococcus viridans* may often be found in the blood; in Banti's disease the blood is sterile. A duration of ten years is not uncommon in Banti's disease, whereas subacute bacterial heart disease runs its course in a few months to two years. Periodic remissions and exacerbations may occur in both.—*New England Journal of Medicine,* January 29, 1931, cciv, 5.

Zoster, Varicella, and Encephalitis.—W. Russell Brain, writing in the *British Medical Journal,* January 17, 1931, i, 3654, expresses the opinion that, as herpes zoster is regarded as due to a virus which is quite distinct from that responsible for herpes febrilis, it would be advantageous to confine the term herpes to the latter disease, and to speak of herpes zoster simply as zoster. It is important for clinical purposes to distinguish two types of zoster —symptomatic, that occurring during the course of certain intoxications, and idiopathic, the cause of which is not known. In addition to zoster in its commonest form with cutaneous eruption and sensory disturbances, zoster may invade the gasserian ganglion. At times it may affect only the ophthalmic division, giving rise to corneal lesions or ocular paralyses. The geniculate ganglia may be invaded causing facial paralysis, or typical zoster vesicles in the auricle, or sensory loss in the anterior two-thirds of the tongue. If the facial nerve is involved, it may cause lower motor neurone lesions. Occasionally it invades the joints, and it may give rise to meningitis and encephalitis. Zoster infection of the meninges is indicated by inflammatory changes in the cerebrospinal fluid. Zoster in one individual may be followed after ten days by varicella in a contact. The converse also holds good, and all possible combinations of these associations have been recorded. It has been found that nearly all zoster-from-varicella cases occur in adults, while almost all the varicella-from-zoster patients are children. This difference in age incidence seems to require an explanation in terms of immunity. Adults are relatively immune to the varicella virus, but this immunity wanes as life goes on and the adult who becomes susceptible develops zoster rather than varicella. Brain analyzes 32 cases of varicellar encephalitis recorded in the literature. In half of the cases the conspicuous feature was disturbance of coordination, with or without involuntary movements. The spinal lesion usually produced the picture of a transverse myelitis at the dorsal level of the cord. The prognosis in this condition is good as to both life and recovery of function. A comparative study of varicellar encephalitis, measles encephalitis, and post-vaccinal encephalitis indicates that the clinical pictures, mortality rates, and progress as to functional recovery are quite different in the three conditions. Those who regard them as due to the same virus will have to suppose that the action of this hypothetical organism is hypothetically modified by the influence of the different pre-existing infections. It would seem less speculative to suppose that the differences are due to the encephalitis being produced by different organisms.

The Moro Apple Diet in Diarrhea.—Writing in the *Deutsche medizinische Wochenschrift,* of December 26, 1930, Siegfried Wolff recommends a diet of finely grated apples in diarrheal conditions in very young children. He has used it in 150 children suffering with acute and chronic diarrhea, among whom were five cases that were clinically dysentery with bloody stools. Moro's name is attached to the method because it was he who first subjected this old folk remedy to extensive clinical tests, and found it astonishingly effective. Ripe, mellow apples are peeled, the seeds and cores carefully removed, and the flesh of the apples reduced to a fine pulp by grating on a glass grater. Of this substance a child receives 100-200 gm. at every mealtime, with no other food whatever. No medicine is given, nor are enemata administered. The children are well satisfied with the diet and do not ask for anything more. In case of extreme thirst or on

very hot days dehydrated children may have an occasional drink of cold water or tea and in case of marked loss of weight saline or glucose injections may be given subcutaneously The rule of no other food by mouth must be strictly observed In nearly 100 per cent of cases the cure of the diarrhea was prompt and complete The diarrhea or vomiting stops immediately, and in most cases constipation sets in, or a formed stool is evacuated on the second day at latest But the usual course is that a child who has been having 10 or more stools on the day prior to the treatment will have one or two stools after the first apple meal, and then no more until a mixed diet is restored After the second apple day a transition diet is given, rich in protein milk poor, and vegetable free Rarely diarrhea returns when a normal diet is resumed, in which case one or two more apple days may be carried out The protocols of three typical cases and of three very severe cases are given Two of these children were moribund when treatment began, and the third had been lying 12 hours in writhing pain All responded immediately to the apple pulp, as soon as it passed the intestine Treatment in these cases was prolonged four days and repeated after an interim if the stools showed a tendency to become soft again

The Importance of General Medicine in the Practice of Otology—In his presidential address before the American Otological Society, D Harold Walker emphasized the fact that the field of otology has grown so rapidly that the preparation of those entering the specialty must be broadened Forty or fifty years ago the term otologist was applied to those who were purely and simply aurists At the present day there is a broadening of the outlook from a surgical standpoint New fields are being added — intracranial surgery, bronchoscopy, esophagoscopy There are, however, as many medical problems as there are surgical, and, as a rule, they are more difficult to solve To the man who intends to specialize in otology a medical internship would be more valuable than a surgical one When the young graduate begins his practice he finds that there are many medical conditions which he must meet The examination of the blood, the chemistry of the cerebrospinal fluid, intracranial pressure, etc, are very important It is in private practice where the non suppurative conditions are met that the weakness in the treatment by otologists is most apparent Headache is a very important symptom and calls for a most thorough examination, for there are numberless causes of headache which may be more or less easily found and here one must not omit one of the most common and important causes namely, constipation Practically every deaf person complains of having had constipation for years Vertigo is another very common symptom, to which unfortunately the name Ménière's disease is still attached Cases are often met in which the diagnosis lies between toxic neuritis and an acoustic tumor Walker cites several cases in which intracranial operation was avoided by the simple removal of some carious teeth or infected tonsils The patient with tinnitus requires a thorough medical examination, including the circulatory system and the endocrines Young men who specialize in otolaryngology should be made to appreciate that the treatment of deafness must necessarily occupy a large portion of their time, and in order to be successful they must be willing to be patient and cheerful, and to sacrifice time The problem of deafness is, to Walker's mind the one where the specialist shows the greatest weakness and fails most often, because he is not willing to make the sacrifice to help these deaf people Deafness must be prevented, and until there is an educational propaganda spread among family physicians, school teachers, and parents and also among the specialists the problem will never be solved Its solution lies very largely with the otologists —*Laryngoscope*, January, 1931, xli 1

Causes of Success and Failure in the Irradiation of Graves' Disease—P Hess and H Schlecht say that roentgen irradiation in Graves' disease is a very effective mode of treatment and gives results equal to those of surgery, with the advantage of no mortality, if it is applied cautiously Adequate doses are, however, required, and sufficient time must be allowed for them to take effect This is a matter of capital importance From 3 to 24 months must be allowed, with an average of 16 months Improvement begins in four weeks, and goes forward steadily If quick results are desirable for social reasons, surgery should be advised The authors' technique consists in three series of treatments, each comprising three sittings on three successive days, with an interval of 4-6 weeks between series At every sitting both sides of the neck are irradiated and also the thymus gland, each with 1/3 E S D, using crossed rays with exposure of the anterior parts of the larynx Thus a total dose of about 50 per cent is striven for in every series Treatment is always given with due regard to the basal metabolism, which is under constant surveillance Of about 80 cases treated in recent years, it has been possible to follow up 41 with examinations covering a period of over one year These include cases of pure hyperthyreosis, of light and also of very severe form

The follow-up has frequently shown that it is precisely in the most severe cases that retrogression of all symptoms has occurred in the course of time to an extent they had not dared to hope for. This has led them to believe that irradiation offers a very active weapon against the disease, one which is equal to surgery, and the correct use of which results in cure in the majority of cases. Of the 41 cases treated and followed up, 16 were cured, 16 improved, and 9 unchanged. The improved cases are those in which there has been complete retrogression of general symptoms, and improvement of organic symptoms, which regress more slowly. Omitting 12 cases which for one reason or another dropped out of sight before cure was complete, the results are: Total, 29; cured, 13; improved, 14; unchanged, 2. Irradiation must be supported by an internal dietetic and medical treatment. All cases are suitable for the treatment, with no contraindications.—*Münchener medizinische Wochenschrift,* January 9, 1931.

The Etiology of Psoriasis Vulgaris.—Florio Sprecher, in an article in the *Riforma medica* of December 15, 1930, says that the pathogenic agent of psoriasis vulgaris is still unknown. Some investigators have thought that it is due to a special morbid constitutional state, hereditary or acquired, such as arthritism, herpetism, gout, uricemia, altered metabolism, and the like. On the basis of a personal case, Sprecher repudiates this view, and holds that the affection is attributable to an exogenous infective agent, and has all the characteristics of dermatoses that spread from this cause. In the case here studied, in a man of 23, who had been the subject of innumerable tattoos 6 years previous, the dermatosis had exactly followed the outline of the patterns. After every implantation of the needles in the skin in making the tattoos, the two operators had, as is customary, cleansed the surface of the tattoo with their lips, wet with saliva. Although one of the two operators was presumably affected with tuberculosis, there was no indication that the infection transmitted was of this type, since the patient remains a robust individual and all tuberculin reactions have been negative. Furthermore, this reaction is negative in the great majority of cases of psoriasis. The fact, now well established by documentary evidence from all countries, that by producing traumata of various kinds on the healthy parts of the skin of a psoriatic patient efflorescences of his dermatosis can be reproduced, is of great significance, since it puts psoriasis in the class of skin diseases that are certainly provoked by an infectious agent. Its mode of spread from a punctiform center toward a constantly widening periphery accords perfectly with that of dermatoses due to external infections. The eruption begins on tracts of skin that have been subjected to attrition or other continuous trauma; its successive spurts continue to choose the cutaneous regions which are the most greatly subjected to irritation. They heal without a trace, but readily recur, always at the old site, where attrition or irritation is greatest. The histopathologic changes are exclusively epidermal and superficial. These considerations, together with the ready transmission of the affection from man to man and from man to animals and vice versa, point unmistakably to the infective nature of psoriasis vulgaris.

A New Form of Mental Inhibition in Children—Epileptic or Epileptoid.—Gilbert Rodin, writing in the *Bulletin de l'Académie de Médecine,* of December 30, 1930, describes a form of mental inhibition which is distinct from that due to emotive causes, and is more correctly termed an obtusion, since it is a temporary suspension of the intellectual faculties, with the mind veritably absent. This absence involves the thinking faculty alone and not the consciousness nor the sensibility, as in classic absent-mindedness. Children of this kind are found to exhibit the epileptoid constitution, having attacks of anger, impulsivity, turbulence, nightmare, nocturnal agitation, somnambulance, and persistent enuresis. There is usually an heredity of syphilis, alcoholism, epilepsy, or emotive and anxious agitation. Epileptoid inhibition may assume different forms. It may resemble bradypsychia, as in children who reply after a prolonged pause, as if stopping to assimilate the question. Again it may appear less an inhibition than as a kind of distraction, which can be diagnosed when other epileptoid signs are present. Here belong those children who forget the errand on which they have been sent, and children who skip over words in a dictation or recitation without noticing that they do so. The condition is not simply one of bradypsychia, because the inhibition persists as long as the question is maintained; there is an intellectual void. Nor is it to be mistaken for a postparoxystic state of torpor, for it may appear without any previous epileptic manifestation, and its diagnosis derives its importance from this fact. Its exact place lies between bradypsychia and absent-mindedness, and it serves as a link between these two manifestations. It is of first importance that this condition be properly diagnosed when the child reaches school age. Excellent therapeutic results have been reached by treatment with phenylethylbarbitalum, accompanied by arsenobenzol, mercury, or bismuth injections, even where there is no precise luetic etiology.

LEGAL

THE OWNERSHIP OF X-RAY PLATES

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

Your counsel is frequently asked the question as to whether a patient has a right to demand X-ray plates which have been taken by a physician or which may be in the actual custody or control of a physician although not actually taken by him. It seems singular that this question has never been passed upon by the courts of this or other States, but such seems to be the fact Our own research has not disclosed any decisions passing upon the question under consideration, and the research of others seems to be the same effect. For example, in a very interesting paper entitled, "The Legal Aspects of X-ray" which appeared in the journal of the Michigan State Medical Society in October, 1930 the author, Dr. S. W. Donaldson says:

"The proprietorship of the films has been an oft discussed question but apparently has never been carried to the higher courts."

We have had occasion to have been consulted on a few occasions by members of the medical profession in cases where a disgruntled patient had demanded possession of X-ray plates in the doctor's possession, threatening if the doctor did not give them up to take out a summons in the magistrate's court charging the doctor with unlawfully withholding property belonging to the patient. Such a demand of course carries with it very clearly a probable lawsuit for malpractice. In such a case, where no express adjudication has been made by the courts, a physician is naturally reluctant to become embroiled in a proceeding in the magistrate's court and hence, rather than subject himself to a distasteful experience in the magistrate's court with its attendant loss of time, the doctor's desire naturally is to return the plates. We, however, have always cautioned the physician before doing so to have prints made of the plates and also to make a careful reading of the plates and reduce to writing exactly what condition is disclosed by the X-ray plates.

How the courts would rule if the question were squarely presented, it is of course difficult to say. On principle it would seem that the X-ray plates should not belong to the patient but should be considered the property of the physician. In that respect we believe that a proper analogy could be drawn to the case of a commercial photographer upon whom demand is made for the negative of a picture taken by him. There can be no question that the sittee in such a case has a right to control the use of the photograph, and the photographer may not use such picture for advertising purposes or for the purposes of trade except upon the express consent of the sittee. To do so would clearly be a violation of the Civil Rights Law of this State which provides in Section 50 thereof as follows:

"Right of privacy.—A person, firm or corporation that uses for advertising purposes, or for the purposes of trade, the name, portrait or picture of any living person without having first obtained the written consent of such person, or if a minor of his or her parent or guardian, is guilty of a misdemeanor."

However, while the sittee has the right thus to control the use of the picture, we believe that the courts would hold (although there is no express adjudication on this point either) that the negative was the property of photographer.

It seems clear that as to X-rays taken in a hospital these would form part of the hospital record and the patient could not legally demand possession of them. In a recent case in a court of a nearby State, although there was no question involved of the property rights of the X-ray pictures, the language of the court in discussing X-rays taken in a hospital is very significant. On this point the court said:

"* * *there was undisputed evidence that the X-rays taken in the hospital, as these rays were, are considered hospital property; hence they are not taken except on order of the physician or surgeon, that the X-ray pictures are indexed and numbered as part of the hospital record, that from the pictures the radiologist makes findings in writing, which are a part of the X-ray laboratory records and held there as a part of the records of the hospital."

As we have already said, it is difficult to speculate as to what the courts would do if the question involved here were squarely presented, but we believe that the resolutions adopted by the Radiological Society of North America on this point is not only good common sense but good law as well, and it undoubtedly expresses the belief and understanding of physicians generally upon this point. In those resolutions it was said:

"That all roentgenograms, plates, films, negatives, photographs, tracings or other records of examinations are the property of the roentgenologist who made them or the laboratory in which they were made."

In commenting generally upon the subject under consideration, Dr. Donaldson in the paper to which reference has already been made says:

"The roentgenologist acts as a consultant and in obedience to the professional code of ethics is not to make known any findings or conclusions to the patients, relatives, friends or anyone directly or indirectly connected with the case other than the requesting physician. General acceptance by the profession of these principles and existing rules in many hospitals will go a long way if ever this question comes before the courts. When a patient presents himself for an examination he agrees to be examined in whatever way may be necessary to make a diagnosis and there is no reason to assume that he owns the films any more than there is reason to believe that he owns the dictating machine cylinder the doctor used in making the report or to ask that his temperature chart be turned over to him when he is discharged from the hospital. Some laboratories have a rule, a copy of which is on their receipt, stating that films may be demonstrated to patients on written consent of the referring physician and are open to inspection to any reputable physician who may show a legitimate interest in the case, or subject to subpoena the same as any other hospital records."

CLAIMED NEGLIGENT TREATMENT OF FRACTURE OF RADIUS AND ULNA

In this case a woman about seventy years of age was thrown from a wagon by a runaway horse, causing her to fall upon her left arm. She sustained a compound comminuted fracture of the distal portion of the radius and a simple fracture of the ulna. The patient, in a state of profound traumatic shock, her pulse barely palpable, was brought to a hospital for emergency treatment. The chief surgeon of the hospital examined her and caused X-rays to be taken. Her general condition was very poor, disclosing arteriosclerosis, shock, senile dementia, high blood pressure and poor quality of pulse. The surgeon dressed the wound, but because of the probability of infection, the protrusion of the bone and the poor condition of the plaintiff, he considered that to operate under a general anaesthesia or to manipulate the fracture would probably result fatally to the patient. Therefore, the fracture was partially reduced, using a minimum of manipulation and applying a splint. The patient was given pneumococcus vaccine and antitetanus serum.

Two days after her entry into the hospital she developed pneumonia, and because of her previous poor condition she became critically ill. However, her condition improved and she was discharged about 10 days later. At the time of her discharge she was told that her fracture needed further attention, but because of her weakened condition nothing could be done then and she was directed to return about a month later for further treatment. This she did not do.

Thereafter, a suit was instituted by the patient charging that the failure to properly set her arm had caused a deformity. For some reason the plaintiff named as defendant not the doctor who treated her but another doctor associated with the said surgeon who had never treated her in any way except to change her dressings.

The case was never pressed by the plaintiff's attorney for trial and after the Statute of Limitations had run as to a claim against the physician who actually cared for the plaintiff, the defendant's attorney brought the case on for trial and as the plaintiff or her attorney did not appear in court to proceed with the case, a dismissal of the complaint was obtained, thereby terminating the entire matter in favor of the defendant.

CLAIMED IMPROPER TREATMENT OF FRACTURE OF RADIUS

In this case a patient was brought to the doctor's office complaining that she had fallen in her home and broken her arm.

Upon examination the doctor found an impacted fracture of the radius. He thereupon reduced the fracture, applying anterior and posterior splints, and caused an *x*-ray picture to be taken directly after the application of the splints. The *x*-ray report showed that apposition and alignment were good.

The patient returned to the doctor's office every three or four days and the doctor renewed the bandages about the splints to keep them tight until about two weeks had elapsed, at which time he removed the posterior splint and rebandaged the arm leaving the anterior splint in place. At the end of the fifth week he removed the anterior splint. At this time the doctor found good union to be present, although there was some limitation of motion of the wrist. Massage was then

suggested and the doctor heard nothing more of the patient until some months later when he learned that another doctor had caused an *x*-ray to be taken, which report read as follows:

"Radiographic examination of the right wrist shows a deformity of the ulna approximately one and a half inches above the articulation. This exhibits an internal and palmer bowing. The mortise between the radius and ulna appears somewhat wide."

The doctor was informed that at the time of the second *x*-ray report the patient had satisfactory use of her arm with the exception of inal to apply strength in her grip.

A law suit was instituted against the dc charging that the defendant had improperl the bones in the plaintiff's arm and had give improper aftercare, as a result of which plaintiff had suffered much pain and a perma deformity. The suit was not promptly pre for trial and before the action could be rea in its regular order for trial, the defendant dc died. The plaintiff's attorney therefore sented to discontinue the action.

CLAIMED NEGLIGENT POST-OPERATIVE TREATMENT OF CLUB FEE

In this case a girl, seventeen years of age, was brought to the defendant doctor. She was suffering from congenital club feet.

It was arranged that she be operated upon in an attempt to correct the condition. She went to a hospital and an operation was performed upon her feet, which consisted of a cuneiform osteotomy of scaphoid, tenotomy of tendon achilles (the astragalus had previously been removed), separation of metatarsal and cuboid, correction to overcome varus. A portion of tuberosity was removed at the fifth metatarsal. Both feet were placed in plaster casts and the girl was removed to her room where she came out of the ether in good condition.

The defendant-surgeon attended the girl the next day and she appeared comfortable and needed no adjustment of the casts.

That same day the defendant left for a trip abroad and placed the girl in charge of his associates at the hospital. The girl thereafter ran a temperature and complained continuously of siderable pain in one foot. The cast was rem from that foot and her condition did not impr and seventeen days after the operation the pa developed lobar pneumonia, from which she three days later.

An action was commenced against the def ant-doctor charging him with the responsit for the girl's death in that he failed to perso remain in charge of her case and left her in care of incompetent doctors who permitted casts to remain on the feet for an impr length of time, which, it was asserted, ca gangrene to set in and as a result the girl The true facts were that no gangrene had developed.

When the case was brought on for trial plaintiff failed to appear and a motion was n on behalf of the defendant to dismiss the c plaint, which was granted, thereby termina the matter in favor of the defendant.

ALLEGED NEGLIGENCE IN TONSIL AND ADENOID REMOVAL

A child about two and one-half years of age was referred to the defendant doctor in order that a tonsillectomy and adenoid operation be performed upon him.

Subsequent to said operation an action was instituted on behalf of the child by his guardian ad litem against the doctor, in which it was claimed that the defendant conducted himself so negligently and carelessly in the removal of the plaintiff's tonsils and adenoids as to permit inflammation and infection to develop in his nose and throat, thereby damaging him greatly.

In the plaintiff's bill of particulars it was specified that the particular manner in which the defendant was negligent was that he inserted a sponge in the plaintiff's nose or throat and failed to remove said sponge, which remained therein, to the detriment of the child's health. It was charged that this negligence caused the child to be confined to his bed for a period of about one month due to an infection and a subsequent distribution of pus throughout the body, wl caused fever and pain.

It appeared, however, that the doctor formed the operation with all care. The ton were removed by the snare method, and patient bled but slightly. Gauze sponges w placed into each tonsil cavity and the nasal pl ynx. These pieces of gauze were attached strings, and after the bleeding receded the do removed the sponges and carefully checked determine that all were removed. The do contended that all charges of negligence w false.

After the case had been noticed for trial, before it could be reached in its regular or the doctor died and a motion was made to disn the summons and complaint on the ground t the action abated by reason of the death of defendant. Said motion was granted, thus ter nating the matter.

NEWS NOTES

PUBLIC RELATIONS SURVEY, NUMBER 18, TOMPKINS COUNTY

The members of the Tompkins County Medical Society enjoy intimate and cordial relations with all the public health activities of the county, in the formation and administration of which we have been active, either as an organization or as individuals. We are aware of the trend in Medical affairs and are in sympathy with the same.

The Ithaca Tuberculosis Association was formed about twenty years ago, during which time, with one exception, the president has been one of our members, with three or four other physicians associated with him on the board of directors.

The Open Air School and the Cayuga Preventorium were both initiated by the Tuberculosis Association. The Cayuga Preventorium, founded fifteen years ago, as the first in the state, has a physician as president with three others on the board.

The appointment of a full time health officer for Ithaca and the establishment of the County Tuberculosis Sanatorium were both approved and urged by the society. The need of a County Laboratory was pointed out, an efficient committee was appointed to confer with the Board of Supervisors, and the end was achieved.

We are also represented on the board of directors of the County Health Committee, the Tompkins County Conference of Public Welfare agencies, and the Reconstruction Home for Infantile Paralysis.

Various clinics are held weekly or monthly, in various fields, which include, tuberculosis, baby care, and work along prenatal, genito-urinary, mental, and orthopedic lines.

The toxin-antitoxin campaign in the county has been well carried on by the city, village and town health officers with the assistance of the school nurses and the nurses of the county health committee who cover the rural sections.

The campaign against cancer has been carried on by newspaper publicity and a public lecture.

Much time has been given to the consideration of a County Health Unit, and while we are agreed in many ways to the principle of such an organization, we feel that possibly our problem can be solved better by a modification of the plan adapted to local conditions. If we recommend such a step, we wish to be sure our plan will be to the best interest of all concerned.

This report does not indicate any activity of the Public Relations Committee during the past year, but does draw attention to the fact that the medical men of Tompkins County have been and are aiding, influencing, and initiating public health activities.

The laymen of the county who are interested in public health have done excellent work, the results of which are of benefit to all. The Board of Supervisors has always cooperated generously when the need and public approval have been demonstrated.

H. E. MERRIAM, *Chairman,*
Committee on Public Relations
Tompkins County Medical Society.

TRI-STATE CONFERENCE

The seventeenth session of the Tri-State Conference was held in the Hotel Pennsylvania, New York City, on February 28, beginning at 10 o'clock. There were present:

From New Jersey:

Dr. G. N. J. Sommer, Trenton, President of the State Society;

Dr. J. F. Hagarty, Newark, Vice-President;

Dr. J. B. Morrison, Newark, Secretary; and

Dr. S. T. Snedecor, Hackensack, Councillor Second District.

Dr. H. O. Reik, Atlantic City, Editor.

From Pennsylvania:

Dr. H. Walbertson, Scranton, Past President;

Dr. Ross Patterson, Philadelphia, President;

Dr. W. F. Donaldson, Pittsburgh, Secretary;

Dr. Frank Hammond, Philadelphia, Editor.

From New York:

Dr. W. H. Ross, Brentwood, President;

Dr. J. S. Lawrence, Albany, Executive Officer;

Dr. Frank Overton, Patchogue, Executive Editor.

Dr. Lawrence led a discussion on the subject: "What are State Departments of Labor Doing to Advance Industrial Surgery?" His special contribution was a description of the psychology of the administrative officials of the Department of Labor, and also that of the physicians who do industrial surgery and compensation work. A great need is that a law should be passed authorizing the appointment of a medical representative on the advisory committee to the Commissioner of Labor.

The running remarks of the members of the conference made in the course of the round-table discussion, disclosed a great similarity in the administration of the labor departments of the three States, and the existence of the same problems in them. The impression was confirmed that education, rather than legislation, would solve the difficulties in executing the provisions of the Workmen's Compensation Acts.

Luncheon was served at one o'clock with the Medical Society of the State of New York as the host; after which Dr. Ross outlined the legislative work which has been suggested by the Commission.

Dr. Snedecor described the progress made in New Jersey in initiating the plan of holding meetings in each Councillor District, as in New York and Pennsylvania. He referred to the discussion in the Conference of County Secretaries and Reporters, which was held in Trenton on November 5, 1930, and was reported in the NEW YORK STATE JOURNAL OF MEDICINE of January 1, 1931, page 48; and described the meeting of the First Councillor District held in Newark, a of the Second in Jersey City. The officers the Second District will assemble in April a will listen to reports of the members to wh have been assigned the following topics:

1. Legislation.
2. Credentials of specialists.
3. Examination of preschool children.
4. Administrative methods of diphtheria i munization.
5. Publicity and advertising by County Me cal Societies.
6. Supervision of free medical service.
7. Administration and supervision of cour health departments.

Dr Snedecor called attention to the fact th the Councillors of New Jersey had the adva tage of starting something new to them; and th could profit by the experience of New York a Pennsylvania. He hoped that the Councill would develop definite activities which would recognized by the State Society and incorporat in its rules and regulations.

LEGISLATION

BULLETIN NO. 5—FEBRUARY 19, 1931

Since issuing the last bulletin, the following bills have been introduced:

Senate Int. No. 741—Hastings, creates a temporary commission to study economic effect of sickness on the working life of human beings, best method for state to cooperate to prevent and cure sickness and by which compensation for unemployment caused by sickness may be effectuated, and appropriates $15,000.00. Referred to the Finance Committee.

Senate Int. No. 744—Love (Assembly Int. No. 980—Story), amends the Workmen's Compensation Law by striking out list of occupational diseases and providing compensation shall be payable for any occupational disease or illness which it shall be established by medical testimony was directly due to or caused by any employment enumerated in subdivision one. Referred to the Labor Committee.

Senate Int. No. 837—Wicks (Assembly Int. No. 1158—Stevenson), adds a new article to the Public Health Law, providing for the establishment, maintenance and acquisition of tuberculosis hospitals and providing for management and operation thereof as state institutions. Referred to the Finance Committee.

We understand the Governor's Commission recommended the erection by the state of three additional tuberculosis hospitals, and legislation to that effect may be awaited.

Senate Int. No. 870—Love (Assembly Int. No. 1249—Story), amends the Civil Service Law providing for the medical examination of vetera before they shall be disqualified from holding a position in civil service because of physical di ability. Referred to the Civil Service Committe

The law enacted last year which gave disabl veterans preference in civil service examinatio where they are competitors, is causing the civ service considerable difficulty. They have fou it necessary to have physical examinations ma of veterans competing in an examination in ord to establish their disability before lists of su cessful contestants can be established. We are i formed that several civil service lists are bei held up at present for this reason.

Assembly Int. No. 991—Coughlin, adds ne section to the General Municipal Law for crea ing a division or bureau for supervising treatme of indigent ill. Referred to the Cities Committe

Action on Bills

The Hickey optometry bill, Senate Int. N 441 (Assembly Int. No. 727—Piper), has ad vanced to third reading in the Senate.

BULLETIN NO. 6—FEBRUARY 26, 1931

Since the last bulletin was issued, the following bills have been introduced:

Senate Int. No. 915—Fearon (Assembly Int. No. 1277—Tellier). This is the osteopathic bill and the most vicious bill that they have ever presented. In the twinkling of an eye it would create medical practitioners skilled in the use of drugs out of men who have received no training in the prescribing of drugs. The bill deletes from the law all restrictions with regard to the use of drugs by osteopaths; and then, at some length, describes what limits there shall be to their performing surgery; namely, a license to practice osteopathy shall not entitle the holder thereof to perform any surgical operation involving incision for the opening of a natural body cavity, for the removal of cancer, for the amputation of an extremity or an appendage, or for the removal of any gland or organ, or part thereof, of the human body. The author of the bill apparently feels that cancer is well defined so that an osteopath would as readily recognize a cancer as he would an arm or a leg. In our opinion, the most serious part of the bill is that which permits the osteopaths unlimited use of drugs. Action on this bill will be hastened. We are authoritatively advised that the Education Committee, with whom the bill rests, will take action upon it on Tuesday. May we urge every physician who receives this bulletin to get in touch immediately with his legislators, registering his opposition, and particularly those who have as legislators members of the Education Committee.

Senate Int. No. 917—Lord (Assembly Int. No. 991—Coughlin), provides in the General Municipal Law for the creation of a division or bureau for supervising treatment of indigent ill.

Senate Int. No. 993—Wicks (Assembly Int. No. 1362—Hutchinson), amends generally the Public Health, State Charities, Public Welfare, Conservation, Village, Town and County Laws, and makes an appropriation for state tuberculosis hospitals and sites. This is the bill that embraces the recommendations of the Governor's Health Commission. It is a voluminous bill and has not yet been printed.

The Porter chiropractic bill—Assembly Int. No. 636—has been amended. The new print is No. 1346. The amendments make it conform more strictly to provisions of the medical practice act. However, it still contains the following objectionable features: The examining board shall be a specially constructed board, appointed by the Regents from the chiropractors who are practicing in the state at the present time. The provision states that the board shall consist of three members, all of whom shall be chiropractors who shall have the minimum qualifications specified for applicant for the special examination. It further states that no medical doctor nor osteopath shall be eligible for appointment to the board at any time. It is provided that the *present practitioners* may be licensed by passing before this board a special written examination in anatomy, physiology, symptomatology, including diagnosis of communicable diseases, hygiene, and the theory and practice of chiropractic. One may well wonder how many chiropractors there are in the state who know enough about these subjects either to set or take an examination in them.

Those who make application for license in the future shall be obliged to pass a written examination in the same subjects that are now presented to osteopaths and physicians, but, again, the examination will be before this special chiropractic board. This gives another point of opposition to the bill in that it provides for the creation of a special examining board, a procedure which our Regents have effectively opposed in the past. The definition of the practice of chiropractic is broader than in previous years—it is: "'The practice of chiropractic' is defined as diagnosing and the treating by the palpating and adjusting by hand of the vertebral column *and tissues.*" In the past the chiropractors have maintained that their field lay in the adjustment of the vertebral column, but now they include manipulation of the tissues, and that gives them absolutely the same field as the osteopaths.

This bill will also be acted upon on Tuesday and the warning that was given with regard to the osteopath bill applies here with equal force.

Action on Bills

The Hickey optometry bill—Senate Int. No. 441, has passed the Senate and now rests with the Assembly Education Committee.

Senate Int. No. 344—Cilano—Assembly Int. No. 442—Esmond; Mental Hygiene Law, relative to qualified psychiatrists, has been reported out of committee in both Houses.

* * * * *

On last Tuesday the Assembly Codes Committee gave a hearing on the Vaughan anti-vivisection bill. For the Medical Society the following persons appeared: Dr. Sweet, Chairman of the Committee on Medical Research; Drs. Wyckoff, Hartwell, Rous, Robinson, Linsly Williams, Gerster, Wadsworth, E. MacD. Stanton, and L. F. Schiff.

Arguments presented by these men were very convincing and although the committee took no immediate action, there can be little doubt but that the bill will be killed in committee.

Senate Int. No. 870—Love, offering an amendment to the Civil Service Law in relation to preference allowed veterans. Our particular interest in this lies in the fact that there is already

in the law a preference given to disabled veterans In a civil service examination the disabled veteran shall be given preference over other competitors. The Civil Service Department is having difficulty in carrying out this provision, because it necessitates a physical examination of every veteran trying a civil service examination, in order to establish his disability before preference can be accorded him. Several lists are being held up at present because of the inability of the Department of Civil Service to secure physical examinations.

Assembly Int. No. 636, late Print No. 1346 This is an amendment to the Porter chiropractic bill, the original of which was identical with the McNaboe bill which we sent you some time ago—Senate Int. No. 361. Look this bill over very carefully. The first objectionable feature is that it provides for the creation of a special examining board to consist of chiropractors who are practicing in the state at the present time. The second point is that the definition of chiropractic has been extended to include the manipulation of tissues as well as the vertebral column This would make the chiropractor the equal of the osteopath. Third—while provision is made that no persons shall be licensed except they pass either the special or the regular written examination, these examinations will be before this board of chiropractors who are asked to present only such qualifications as those demanded of the applicant for licensure. It is very cleverly drawn now, but, nevertheless, it aims to admit to practice persons who are not educationally qualified.

Senate Int. No. 915—Fearon, amends the Education Law in relation to the practice of osteopathy. Observe carefully that this amendment would remove all restrictions from osteopaths with regard to the prescribing of drugs; in other words, if this were enacted into law every osteopath would immediately become a physician fully qualified to prescribe drugs, in spite of the fact that he had never received any training with regard to their use. It also would permit him to do surgery within certain limitations, not clearly defined; for instance, who can tell what is a cancer in its early state?

Opposition to the last two bills should be registered immediately, because action will be taken upon them in committee early next week.

BULLETIN NO. 7—MARCH 4, 1931

Since issuing our last bulletin, the following bills have been introduced:

Senate Int. No. 1080—Wicks (Assembly Int. No. 1453—Bentley), authorizes the Greene County supervisors to establish a public general hospital. Referred to Internal Affairs Committee.

Assembly Int. No. 1462—Foody, is this year's version of the methanol bill which Dr. Lattin carried for a number of years. This bill prohibits the sale of food, drink, medicinal or toilet preparations or anti-freeze mixtures for autos containing wood alcohol, methanol, methyl alcohol, or sale of such alcohols except under license and with label. Referred to the Codes Committee.

Assembly Int. No. 1464—Gimbrone, amending the Workmen's Compensation Law. This is a reintroduction of last year's free choice bill. Referred to the Labor Committee.

Assembly Int. No. 1470—Hanley, amends the Workmen's Compensation Law, providing that claims for legal services and medical treatment when approved shall be payable forthwith and deductable only out of last payments of compensation award. Referred to the Labor Committee.

Assembly Int. No. 1500—Sullivan, adds a new article, 11-a, and repeals section 181-a of the General Business Law, relative to nurses' registries. Referred to the Judiciary Committee.

Assembly Int. No. 1540—Cahill, amends section 377 of the Public Health Law, relative to registration of death certificates. Referred to the Health Committee.

Action on Bills

Assembly Int. No. 574—Dickey, making it a violation of article to obtain habit-forming drugs from one physician while receiving treatment from another without disclosing the fact, has passed the Assembly.

Hearings

A hearing has been accorded the anti-vaccination bill and the Love finger print bill, by the joint Health Committees. Anderson, of the Citizens' Medical Reference Bureau, New York City, appeared in favor of the anti-vaccination bill. As in previous years, this bill was introduced at his request. In addition to our Executive Officer, there appeared in opposition, representatives of the State Department of Health; Dr. Darlington, from the New York City Department of Health; and Mrs. Wakely, of Saratoga Springs, representing the Parent-Teachers' Association.

The Assembly Education Committee requested the Executive Officer and representatives of the Department of Education to appear before them on Tuesday to explain the amendments involved in the chiropractic, osteopathic and physiotherapy bills.

The Assembly has adopted a resolution to adjourn on March 28th.

HARRY ARANOW,
WALTER A. CALIHAN,
JOHN J. RAINEY,

Committee on Legislation
Medical Society of the State of New York.

PHYSICAL THERAPY CLINICS OPEN FOR GENERAL PRACTITIONERS

The Committee on Physical Therapy of the Medical Society of the State of New York herewith publishes a list of physical therapy clinics which practitioners are welcome to visit at the times stated. The physician in charge at each clinic will be glad to demonstrate the work so that physicians can become familiar with its scope and later avail themselves of the existing regular postgraduate courses for the thorough study of its theory and practice. There is, of course, no charge for attending any of these clinics:

New York City

Beekman Street Hospital; Daily, 9:00 A.M. to 5:00 P.M. (except Saturday, 9:00 A.M. to 12:00 M.). Dr. Randolph Raynolds and Dr. Wm. B. Snow, Jr.

Hospital for Joint Diseases; Daily, 9:00 A.M. to 4:00 P.M. Dr. Jerome Weiss.

Hospital for the Ruptured and Crippled; Daily, 1:00 P.M. to 3:00 P.M. Dr. K. G. Hansson.

Misericordia Hospital; Daily, 9:00 A.M. to 3:00 P.M. Dr. Robert Muller.

Montefiore Hospital; Daily, 9:00 A.M. to 5:00 P.M. Dr. I. M. Leavy.

Mount Sinai Hospital; Daily, 9:30 A.M. Dr. Heinrich F. Wolf.

Polyclinic Hospital; Daily, 10:00 A.M. Dr. Richard Kovacs.

Vanderbilt Clinic; Daily, 9:00 A.M. to 5:00 P.M. (except Saturday, 9:00 A.M. to 12:00 M.). Dr. Norman E. Titus and staff.

Albany

Albany Hospital; Daily, 9:00 A.M. to 10 A.M. and 3:00 P.M. to 5:00 P.M. Dr. John W. Ghormley.

Syracuse

University Hospital; Wednesday, 2:00 P.M. and Saturday, 9:15 A.M. Dr. J. J. Levy.

Memorial Hospital; Daily, 9:00 A.M. Dr. Lee A. Hadley.

As other approved opportunities are offered, they will be added to this list.

RICHARD KOVACS, *Chairman.*

KINGS COUNTY RESOLUTIONS

The Medical Society of the County of Kings passed four resolutions on legislative subjects at its meeting held on February 17, 1931, and requested their publication in the NEW YORK STATE JOURNAL OF MEDICINE.

The first resolution is in opposition to bill number 4582 introduced in the United States Senate by Senator Frederick H. Gillette of Massachusetts. The bill amends section 305 of the Federal Tariff act of 1922, and sections 211, 245 and 312 of the Federal criminal code. The Tariff Act forbids the importation of articles or literature in which there is involved either lottery, or obscenity, or the prevention of conception, or unlawful abortion. The law implies that some forms of abortion may be lawful, but it also implies that nothing concerned with the prevention of conception is lawful.

The sections of the Federal Criminal Code are of a similar nature, and forbid the mailing, transportation, distribution, or exhibition of practically everything mentioned in the Tariff Act.

Senator Gillette's amendment is intended to exempt literature, information, instruments, and drugs when put out by proper medical authority. That part of the amendment to which Kings County Medical Society objects reads as follows:

"The provisions of this section shall not apply (1) to information relating to the prevention of conception if published either within or without the United States by any governmental agency, medical society, medical school, or medical journal, or if reprinted after such publication, by any person or organization whatever."

The objection is to the second clause which is a sweeping permission that the reprinting may be done by any person or organization whatever. The Medical Society of the County of Kings therefore "Disapproves the provisions of the Bill and opposes its enactment because it not only opens the door for unlicensed and vicious teaching and practice of birth-control, but it also interferes with the freedom of scientific congress among 'medical men in the exchange of their views in medical schools, medical societies and medical journals' in that it authorizes the use and reprinting of such delicate and potentially dangerous material and information, at will, by 'Any person or organization whatever.'"

The second resolution adopted by the Kings County Medical Society was in opposition to a health insurance bill which is described in the resolution as follows:

"WHEREAS: Assembly Bill No. 5 introduced by Assemblyman Cuvillier in the current session of the legislature and described as 'An act to establish a system of compulsory insurance to fur-

nish benefits for employees in case of old age unemployment, death, sickness and accident, not covered by workmen's compensation and for their dependants in case of sickness, accident and death, and to furnish maternity benefits, and to provide for contribution by employers, employees and the State, and to create the health insurance commission' contains all the features that have been objectionable to the Medical Society of the County of Kings in other similar bills introduced in other years, and

"WHEREAS: The Bill, as presented this year, in addition to health insurance, includes old age and unemployment insurance thereby confusing the issues and broadening the appeal for support of a measure designed primarily to fasten on the State and the medical profession a system of compulsory health insurance, therefore be it

"Resolved, that the Medical Society of the County of Kings reiterates and reaffirms the opposition it has consistently maintained against such legislation."

The third resolution was in opposition to Senate Bill, No. 346 amending the mental hygiene law so as to create a Board of Examiners whose membership might include psychologists and other non-medical experts. The ground of disapproval is that the bill "is inimical to the best interests of the medical profession, the administration of justice and the State." The resolution also says:

"Resolved, that it is the sense of this Society that coordinated action within the County Societies and the State Society should be initiated for the purpose of having organized medicine present for legislative consideration a rational and effective measure to standardize and regulate expert examinations and testimony in criminal cases, in relation to the existence of insanity or mental defect on the part of the defendant at the time of the alleged commission of the offense charged."

The fourth resolution was in approval of Assembly Bill No. 588, Senate 386, which "provides for an Act to amend the Civil Practice Act and the decedent estate law, in relation to the survival of actions for personal injury. This is to correct the law so the right of action for personal injuries would survive after the death of the wrongdoer where the law now specifically excludes an action for personal injuries."

GREENE COUNTY

The Board of Supervisors of Greene County considered the question of a County Hospital at its meeting on February 17, and voted unanimously to establish it. The resolution was as follows:

"Resolved, That there be established in and for the County of Greene, pursuant to Sections 45 and 49 of the County Law and 126 of the General Municipal Law, a County Hospital, said hospital to be erected in the Village of Catskill at a cost not to exceed $70,000, including equipment, and to be operated with funds jointly from the State of New York, Department of Public Health, pursuant to said Sections 45 and 49 of the County Law and Section 126 of the General Municipal Law, and funds jointly to be received from the Trustees of the Greene County Memorial Hospital Committee, said Trustees to provide the amount of $35,000 for the erection and equipment of said hospital and also such amounts as may be necessary from the income of the trust funds in the hands of said Greene County Memorial Hospital Committee to meet any deficit which might occur in the maintenance and operation of said hospital."

The establishment of a county hospital for Greene County has been under consideration for several years, and a legacy of $50,000 was available for the purpose. (See this Journal May 15, 1929, page 627.)

A special meeting of the Greene County Medical Society was held on the evening of Thursday, February 26th, for the purpose of discussing the advisability of establishing a county health unit for Greene County. A general meeting, which was open to the public, was first held in the Court House. A meeting of the Health Officers of the County was also called by Dr. F. E. Coughlin, Acting District State Health Officer, to discuss the question, but no official action was taken.

A dinner was served at 7 P. M., after which Dr. William H. Ross, President of the Medical Society of the State of New York, addressed the meeting.

The question of a County Health unit for Greene County was then debated by the members of the Society and some of the members of the Board of Supervisors who were present. No official action was taken, for the sentiment was in favor of awaiting the action of the Legislature in regard to the bill compelling the establishment of county boards of health in all counties by September 1, 1931, as was suggested by the Governor's Health Commission.

W. M. RAPP, *Secretary*.

TOMPKINS COUNTY

The Comitia Minora of the Tompkins County Medical Society met on January 14, and considered ways and means of carrying out the provisions of the Welfare Law. The following principles were formally stated to be applicable to the City of Ithaca:

1. It should be recognized that the Welfare Official can pay for no services (except those rendered in emergency), unless he has previously authorized the same, preferably in writing.

2. The attending physician should report promptly to the Welfare Official at the termination of service on each case; and on prolonged cases make frequent reports of progress or the opposite. He should consider the Welfare Official as the head of the family which he is serving.

3. At the termination of service in each case the physician should at once render his bill for such service and be sure it is properly sworn to.

4. The fees charged by the attending physician should be the minimum fees adopted by the County Medical Society for such cases or the usual minimum fees for such cases.

It was also suggested that there be created a grievance and advisory committee of the society to which may be submitted for adjustment any differences arising beween the physician employed and the welfare official, and, if occasion arises, confer with the Mayor, and, or, with the Finance Committee of the Common Council.

These principles were adopted at the meeting of the county society in January, and were approved by the Mayor of Ithaca.

The Society held a special meeting on February 10 and adopted a minimum fee bill for welfare work (see next article).

The regular February meeting of the Society was held Tuesday evening the 17th, at the Ithaca Hotel, with a fairly full attendance despite a stormy night. Several visitors were present from the Cortland County Society and from Clifton Springs.

A resolution upon the recent death of Dr. Veranus A. Moore, a distinguished member of our Society, was adopted, ordered spread upon the minutes and a copy sent to the bereaved family.

Dr. Howard L. Prince of Rochester then opened the scientific session, speaking on "Vascular Diseases of the Extremities" citing many such conditions and their appropriate treatment. Discussion was opened by Dr. F. J. McCormick, followed by Dr. J. H. Wattenberg of Cortland, Dr. Floyd R. Wright of Clifton Springs, Drs. Martin B. Tinker, H. B. Sutton, and J. W. Papez of Ithaca.

Dr. William D. Johnson of Batavia presented interesting conditions, including Ruptured Liver, Duodenal Ulcer, Peritonitis, Infected Kidney, and Intestinal Obstruction—presenting each briefly, succinctly and to the point in his usual happy and impressive manner. Discussion was opened by Dr. Martin B. Tinker followed by Drs. F. J. McCormick, W. F. Lee, J. H. Wattenberg, H. B. Sutton, and Howard L. Prince.

The members, after passing a vote of thanks to the speakers, enjoyed a buffet lunch and indulged in a general visit before breaking up. The remark was many times heard that this was one of the most enjoyable, interesting and instructive meetings of the season.

FEE LIST, TOMPKINS COUNTY

The following Minimum Fee Bill was adopted February 10, 1931, at a Special Meeting of the Tompkins County Medical Society called solely for the purpose of establishing services rendered to Welfare patients at the request of Commissioners of Public Welfare, and applies only to those Physicians residing in the City of Ithaca, N. Y.

GENERAL

Office call, $1.50.
Day house call, $2.00.
Hospital call, $2.00.
Call outside the City—$3.00 for the first mile outside city; .50 for each mile thereafter, one way.
Night house call received afer 9 o'clock p.m., $4.00.
Surgical dressing at house, $1.00 extra.
Consultation, $5.00.
General physical examination, $3.00.
Gynaecological examination and treatment, $3.00.
Genito-urinary examination and treatment, $2.00.
Cystoscopic examination, $25.00.

OBSTETRICS

Uncomplicated cases, $25.00.
Complicated or instrumental, $35.00.

SURGERY

Minor surgery, incisions, etc., $5.00
Caesarean section, $100.
Dilation and curettage, $25.00.
Salpingectomy, $75.00.
Oophorectomy, $75.00.
Circumcision, $10.00.
Fractures—
Colles, uncomplicated, $25.00.
Arm or forearm, $50.00.
Clavicle, $25.00.
Thigh, $75.00.
Neck of femur, $100.
Leg, $50.00.
Ribs, $20.00.
Fingers or toes, $10.00.
Reducing dislocations, $15.00.
Appendectomy uncomplicated, $75.00.
Gastro-enterostomy, $125.00.
Repair single hernia, $75.00. Double hernia, $125.00.
Prostatectomy, $100.00.
Nephrectomy, $125.00.
Catherization, $5.00.
Resection of rib, $75.00.
Aspiration, $15.00.
Mastectomy, single, $50.00. Radical, $125.00.
Drainage of gall bladder, $75.00.
Cholecystectomy, $100.00.
Hemorrhoidectomy, $25.00.
Transfusion, $25.00.
Intravenous saline, $10.00.
Laparotomy, $100.00.
Hysterectomy, $100.00.
Goiter, $100.00.

ANÆSTHESIA

Surgical—ether or chloroform, $10.00.
Gas—ther, $15.00.

EYE, EAR, NOSE AND THROAT

Mastoidectomy single, $125.00. Double, $165.00.
Removal of cataract, $125.00.
Enucleation of eye, $75.00.
Opening of ear drum, $10.00.
Opening of antrum in office, $5.00.
Sub-mucus resection, $50.00.
Iridectomy, $50.00.
Removal of foreign bodies in cornea, $5.00.
Refraction, $5.00.
Fracture of nose, $25.00.
Tonsillectomy, $25.00.

COURSE IN EARLY DIAGNOSIS FOR QUEENS COUNTY

A special course in early diagnosis has been arranged for members of the Queens County Medical Society through [illegible] of the Society with the Special Health Examinations, the School, and the Queensboro Tuberculosis and Health Association.

The course will be given in the Post-Graduate Medical School and Hospital, 20th Street and Second Avenue, at 8 o'clock on Monday evenings, from March 23rd to April 13th. Four sessions will be held, each consisting of three parts:

1. A lecture on the early diagnosis of a general condition by a member of the Staff of the Medical School.

2. A talk on pre-clinic signs in the same condition by Dr. C. Ward Crampton.

3. The examination of cases and then round table discussion.

The four subjects of the lectures in the course are as follows:

March 23, Early Diagnosis in Surgery by Dr. H. H. Ritter.

March 30, Early Diagnosis in Medicine, by Dr. Herman O. Mosenthal.

April 6, Early Diagnosis in Gynecology, by Dr. Walter Dannreuther.

April 13, Early Diagnosis in Nervous Disorders, by Dr. Michael Osnato.

CAYUGA COUNTY

The 125th annual meeting of the Cayuga County Medical Society was held on December 9th, 1930, at the Pompeian Room in the Osborne Hotel, Auburn, at which 65 physicians of Cayuga County, their wives and invited guests were present. Dr. C. F. McCarthy, president for 1930, presided.

The reports of the officers showed the medical association in a prosperous condition with a balance of $1,000 in the treasury and practically 100 per cent membership of physicians and surgeons of the county identified with the county society and also the Medical Society of the State of New York.

The principal event of the evening was an address by the Rt. Rev. John Francis O'Hern, Bishop of the Catholic Diocese of Rochester. The Bishop showed himself to be familiar with medical affairs, and discussed hospitals with a breadth of view that is unusual even among physicians. His address is published in full on page 330 of this Journal.

THE DAILY PRESS

HONOR TO DR. CHARLES STOVER

The *Amsterdam Evening Record* of March 2, contains the following account of a meeting in honor of Dr. Charles Stover who was President of the Medical Society of the State of New York in 1910:

"Saturday, February 28, was the 80th anniversary of the birth of Dr. Charles Stover, for 50 years a practicing physician in this city; and at a special meeting of the medical staff of the City Hospital recognition was made of the event.

"Dr. Horace M. Hicks said that it is given to very few men to complete their 80th year in full possession of all medical and physical faculties.

"Dr. David Wilson recalled his associations with Dr. Stover during his own boyhood and later as a physician. He said that it was the impression made upon him as a boy by Dr. Stover that created his own desire to become a physician.

"Dr. E. C. LaPorte, in his tribute, declared that the brightest spot in his practice of medicine in Amsterdam was his association with Dr. Stover.

"Dr. Julius Schiller said that one of Dr. Stover's finest characteristics in his ability to disagree with one in a gentlemanly manner. He can disagree to the end and carry no grudge. His disagreement is firm and forceful, and leaves one with as much or more respect for him than at the beginning."

The NEW YORK STATE JOURNAL OF MEDICINE extends its congratulations to Dr. Stover in the name of the medical profession of the Empire State.

CRITICISM OF PHYSICIANS

The *New York Times* of January 21 comments editorially on an article signed "Alice Elinor" in the February *Forum*, written by a nurse in criticism of the doctors who attended her in an hospital. The editorial says:

"She burns with indignation because not one of the dozen specialists consulted during five years of ever-increasing pain made the one examination which would have revealed the cause of her ailment. The fact that she had had two children did not interest the doctor skilled in intestinal disorders, nor his brother who ignored everything but the kidneys, nor the spine man, nor any of the other specialists.

"Her more general complaint of doctors is their failure in diagnosis. The tendency toward specialization might be expected to bring medicine ever further from the arts and closer to science. Yet this patient, like a number of others whose experiences have recently been published, declares that diagnosis has become so hasty and casual that it is hardly better than guesswork.

"It is true that most physicians work under terrific pressure. Many of them lack that rare intuition and knack for diagnosis which make a few famous. The public complaint is not against individual doctors, but against the widening breach between the family and the family physician, who is qualified to direct them to the specialist they really need.

PUBLICITY AND CRIME

The New York *Times* of February 12 has an editorial discussion of the effect of publicity on crime, and says:

"Police Commissioner Mulrooney, addressing the Women's Democratic Union, deplored the effect of the publicity of crime in making new crops of criminals. 'Whenever the newspapers publish details of an unusual crime, it will almost inevitably be repeated,' he said. In two instances when the newspapers failed to obtain the facts of two ingenious swindling devices they never appeared in practice again."

The editorial writer argues that the duty of newspapers is to present the news, and of the Police Commissioner to prevent crime. Psychiatrists know that reading the story of a crime impels others to emulate the criminal. Yet doctors will agree with the editor when he says:

"What really increases the criminal crop is the exploiting in sensational newspapers of the criminals themselves. The 'own story' and 'frank confession' type of journalism is what breeds the spirit of emulation. If there were none of this, the commissioner's troubles would be fewer."

FOSSIL WEATHER

By a study of the annual rings of growth on treetrunks and their sequence, scientists of the American Museum of Natural History have computed how many years ago the logs of long deserted houses of Cliff Dwellers in Arizona were living trees A similar study of the layers of clay in the brick yards of Haverstraw has disclosed the number of the annual floods which deposited the layers The New York *Herald Tribune* of February 22 devotes an editorial to a similar revelation of weather conditions, and says

"Less attention than it deserves has been attracted to a really exciting publication recently from the presses of the United States Geological Survey Out in Wyoming and Utah there existed millions of years ago a lake country not unlike our present chain of Great Lakes but smaller Rocks now exposed in the region have long been recognized as bottom muds and sands deposited in these ancient lakes and since hardened and exposed by the slow alterations of the earth's crust During recent years Mr Wilmot H Bradley of the Survey's staff of geologists has been climbing about over the sides of ravines where these ancient lake beds are exposed measuring thousands of paper thin layers of darker and lighter material which he identifies as annual layers deposited by the ancient lake, like the annual growth rings of trees Thus he has uncovered a record of fossil weather unequaled anywhere The thicknesses or thinnesses the dark colors or the light the percentages of sand or oil or limestone crystals of these ancient lake layers are capable of yielding, he believes, veritable records of temperature and rainfall from those long ago days'

The writer describes the discovery that the layers disclose cycles of weather, one of eleven years, corresponding to the cycle of sun spots, and *one of 21,600 years, possibly representing a* grand cycle of the precession of the equinoxes The writer closes with the remark

Perhaps most exciting of all is the evidence that millions of years ago things were moving with our earth our sun and our weather almost precisely as they do today The same sunspots were repeating themselves every eleven years, the same weather changes were recording the vaster cycle of the equinoxes It is doubtful whether man ever has discovered a historical document of as great interest as these annual records on the banks of Wyoming ravines and canyons

---

PSYCHOLOGICAL EFFECTS OF EINSTEIN'S THEORY

Disclosures regarding the extent of the Universe, the constitution of space, and the nature of physical bodies are often items of front page news in the daily papers, and many have been their theological and metaphysical interpretations James J Montague, in his daily feature "More Truth Than Poetry" in the New York *Herald Tribune* of February expresses a universal human reaction to all these learned dissertations when he writes

I watch the stars perambulate
The avenues assigned them,
Each with its own allotted gait
And wonder what's behind them
Have they more stars, far out in space,
Upon their course to light 'em
The while they run their circling race,
And so ad infinitum?
If I from this terrestrial sphere
My hold some day should sever,
And dropped and dropped, year after year,
Would I just drop forever?

Does our sun have still greater suns
In still more distant places
While round its ether track it runs
Through interstellar spaces?
And must these other suns avoid
By moving with precision
Still bigger suns or be destroyed
In some immense collision?
And up, or down, or maybe out
Are other suns revolving?
And what do they revolve about?
This problem seems past solving

But when with realms of space at last
We all become acquainted
We'll likely find they're not as vast
As they have long been painted
These smallest details we shall know
About the starry legions
And maybe talk by radio
To spaces utmost regions
And yet I feel within my heart
No joyful palpitations—
I may not be here to take part
In these communications

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

CARE OF THE INFANT AND CHILD: A Book for Mothers and Nurses. By HARRY R. LITCHFIELD, M.D. and LEON H. DEMBO, M.D. Octavo of 138 pages, illustrated. Baltimore, Waverly Press, Inc., 1930.

THE MORBID PERSONALITY: Psycho-Analytical Studies in the Structure of Character and Personality. By SÁNDOR LORAND, M.D. Octavo of 181 pages. New York, Alfred A. Knopf, 1931. Cloth, $3.00.

THROUGH THE ALIMENTARY CANAL WITH GUN AND CAMERA: A Fascinating Trip to the Interior. By GEORGE S. CHAPPELL. 12mo of 231 pages, illustrated. New York, Frederick A. Stokes Company, 1930. Cloth, $2.00.

HOW IT HAPPENED. By ADALBERT G. BETTMAN, M.D., F.A.C.S. 12mo of 110 pages. Philadelphia, F. A. Davis Company, 1931. Cloth, $1.00.

PHILOSOPHY OF A BIOLOGIST. By SIR LEONARD HILL, F.R.S. 12mo of 88 pages. London, Edward Arnold & Company: New York, Longmans Green & Company, 1930. Cloth, $1.40.

ABNORMAL PSYCHOLOGY: Its Concepts and Theories. By H. L. HOLLINGWORTH, Ph.D. Octavo of 590 pages. New York, The Ronald Press Company, 1930. Cloth, $4.50. (Psychology Series.)

ORAL DISEASES: A Practical Treatise Offering Diagnostic and Therapeutic Aid to the Practitioner of Medicine and Dentistry. By JAMES J. ZEMSKY, D.D.S. Octavo of 402 pages, illustrated. Brooklyn, New York, Physicians and Surgeons Book Co., 1930. Cloth, $8.00.

CLINICAL ALLERGY particularly ASTHMA and HAY FEVER: Mechanism and Treatment. By FRANCIS M. RACKEMANN, M.D. Octavo of 617 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, $10.50.

ABDOMINO-PELVIC DIAGNOSIS IN WOMEN. By ARTHUR JOHN WALSCHEID, M.D. Quarto of 1000 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $12.50.

THE CLINICAL INTERPRETATION OF BLOOD EXAMINATIONS. By ROBERT A. KILDUFFE, A.B., M.D. Octavo of 629 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $6.50.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 14, No. 4. January, 1931. (Philadelphia Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, $16.00 net; paper, $12.00 net.

ANTE-NATAL CARE: Including the abnormalities associated with pregnancy and a section on post-natal care. By W. F. T. HAULTAIN, O.B.E., M.C. and E. CHALMERS FAHMY, M.B., F.R.C.S.E. Second edition. 12mo of 127 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $2.25.

INFANT FEEDING IN GENERAL PRACTICE. By J. V. C. BRAITHWAITE, M.D., M.R.C.P. 12mo of 140 pages. New York, William Wood & Company, 1930. Cloth, $1.75.

PYE'S SURGICAL HANDICRAFT: A Manual of surgical manipulations, minor surgery, and other matters connected with the work of house surgeons and surgical dressers. Edited by H. W. CARSON, F.R.C.S. Tenth edition. Octavo of 641 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $7.00.

A TEXT-BOOK OF MEDICAL JURISPRUDENCE AND TOXICOLOGY. By JOHN GLAISTER, M.D., D.P.H. in collaboration with JOHN GLAISTER, Jr., M.B., Ch.B. Fifth edition. Octavo of 954 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $8.50.

HANDBOOK OF DISEASES OF INFANTS AND CHILDREN for students and practitioners. By F. M. B. ALLEN, M.D., M.R.C.P. Octavo of 595 pages. New York, William Wood & Company, 1930. Cloth, $5.00.

SURGICAL EMERGENCIES IN PRACTICE. By W. H. C. ROMANIS, M.A., M.B., and PHILIP H. MITCHINER, M.D., M.S. Octavo of 608 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $6.00.

EPIDEMIOLOGICAL ESSAYS. By F. G. CROOKSHANK, M.D., F.R.C.P. Octavo of 136 pages. New York, The Macmillan Company, 1931. Cloth, $2.50.

THE PRACTICAL MEDICINE SERIES. Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Series 1930. Chicago, The Year Book Publishers, 1930. General Medicine. Edited by GEORGE H. WEAVER, M.D., and others. 12mo of 848 pages, illustrated. Cloth, $3.00.

OPERATIVE OBSTETRICS ON THE MANIKIN for students and practitioners. By CHARLES B. REED, M.D., F.A.C.S. Octavo of 314 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $4.00.

LOVETT'S LATERAL CURVATURE OF THE SPINE AND ROUND SHOULDERS. Fifth edition revised and edited by FRANK R. OBER, M.D., and A. H. BREWSTER, M.D. Octavo of 240 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $3.50.

AN INTRODUCTION TO PHARMACOLOGY AND THERAPEUTICS. By J. A. Gunn, M.D., D.Sc. Second edition. 12mo of 233 pages. New York and London, Oxford University Press, 1931. Cloth, $1.50. (Oxford Medical Publications).

THE TREATMENT OF CHRONIC DEAFNESS by the Electrophonoïde Method of Zünd-Burguet. By GEORGE C. CATHCART, M.A., M.D. Second edition. 12mo of 111 pages, illustrated. New York and London, Oxford University Press, 1931. Cloth, $1.50. (Oxford Medical Publications).

BOOK REVIEWS

LABORATORY MEDICINE. By DANIEL NICHOLSON, M.D. Octavo of 433 pages, illustrated. Philadelphia, Lea & Febiger, 1930. Cloth, $6.00.

Laboratory Medicine by Nicholson is one of the best books on the subject that it has been the good fortune for the reviewer to read. In the preface the author states that "the aim of the book is to provide in detail, information on the indications, method and interpretation of useful tests that a medical practitioner should be able to perform. It also outlines the principles and interpretation of the more highly technical diagnostic procedures which may be performed for him at a large laboratory." He has surely attained his aim. The little volume contains a veritable wealth of knowledge so arranged and described that its usefulness is generous. It is impossible to enumerate the contents in a short review, but the entire field of laboratory medicine is fully covered. The author has indeed supplied just the kind of work that will be of inestimable value to the general practitioner, and of great practical assistance to the laboratory worker.

The author is to be congratulated on the original arrangement of the subject. His presentation, too, is practical, and conveys the definite indications, methods and application of any laboratory work which he describes. No practitioner of medicine can really afford to omit this book from his library, if he practices modern medicine.

MAX LEDERER.

TROPICAL MEDICINE. By SIR LEONARD ROGERS, M.D. and JOHN W. D. MEGAW, C.I.E. Quarto of 536 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc. 1930. Cloth, $4.00.

This is a relatively small work for the man in the field or the general practitioner who occasionally encounters tropical disease. There is enough discussion—and authoritative discussion—of etiology and pathology to give the reader an intelligent idea of what it is all about, but the emphasis is placed on the practical problems of recognition and handling of the characteristic maladies of hot countries, particularly India.

T. H.

DISEASES OF THE EAR. By PHILIP D. KERRISON, M.D. 4th revised and enlarged edition. Octavo of 627 pages, illustrated. Philadelphia and London, J. B. Lippincott Company, (c. 1930). Cloth, $7.50.

There is an excellent chapter on the anatomy of the ear which would be enhanced if the author were to enlarge his illustrations. Those on the radical mastoid are poor, and should be enlarged.

Mention is not made of the Electric Otoscope. This is of value after examining an ear with the ordinary speculum, in small babies, in consultation in the home, and for those who have not microscopical eyes.

The chapter on functional testing omits the use of the audiometer based on the vacuum tube principle first described by Guttman in 1921, and developed the following year by the Western Electric Co. This instrument is fast superseding the tuning forks and will be in the hands of every otologist as soon as he recovers from his losses in Wall Street.

Diabetes as a cause of furunculosis, pus and polypi coming from the antrum, and the radical mastoid operation causing a serous labyrinthitis are not mentioned. The chart differentiating the various forms of labyrinthitis could be dispensed with and replaced by that of Neuman. Some men will disagree with the author in giving the Gradenigo-syndrome as an indication for a mastoid operation. Occurring in an acute otitis it may clear up without operation. A polyp on the promontory can be removed with a strong solution of Silver Nitrate and Enzymol in a great number of cases without recurring or danger to the labyrinth and without doing a radical mastoid.

The Kobrak test is not mentioned nor is Primary Jugular Bulb thrombosis described. There are several other methods of differentiating a sinus thrombosis occurring in a double mastoiditis, beside the Tobey-Ayer test. Mention is not made of Fowler's interesting contributions on the relation of sinus infection to ear disease. Nor does the author quote from Eagleton's many papers on intracranial complications which should be read over and over again by every otologist.

The chapters on the chronic ear, facial paralysis, and Acoustic tumors are excellent. This is an interesting book and should be read by every otologist.

H. W. RUBIN.

DISEASES OF THE SKIN. A Text-book for Practitioners and Students. By GEORGE CLINTON ANDREWS, A.B., M.D. Octavo of 1091 pages with 988 illustrations. Philadelphia, W. B. Saunders Company, 1930.

From the number of new books devoted to dermatology which have appeared during the past few years together with new editions of the older works on this subject; it would seem that a new work on diseases of the skin was not needed, but even a cursory review of Dr. Andrews' book shows that it is both timely and of great value.

Dr. Andrews has added much material in his book which is not found in the older works. He has made a radical change in his arrangement of the different divisions of his subject, for example, etiology and pathology are considered in one section and not taken up with each separate disease. Under the heading of Classification he has given the older ones. This is interesting and instructive. The application of physiotherapy to this branch of medicine is most excellently explained. The physics of X-rays and Radium is complete. The newer Grenz rays are also described with indications for their use.

The bibliography is extensive. The description of the different conditions affecting the skin is good. The photographs have been well chosen. In brief, the reviewer can find only praise for the work. It should be in every physician's library, both specialists and general practitioners; and for students it deserves to rank with the classical Introduction to Dermatology of Norman Walker.

The mechanical construction of the book is good. The printing is clear, the paper and binding are excellent.

BINFORD THRONE.

CONGENITAL CLUBFOOT. By E. P. BROCKMAN, M.Chir., F.R.C.S. Octavo of 110 pages, illustrated. New York, William Wood & Company, 1930. Cloth, $4.00.

Dr. Brockman has produced an excellent treatise on clubfoot, or rather on the subject of congenital equinovarus not including the other congenital deformities of the foot usually considered under this classification in America. This book won the Sir Robert Jones Gold Medal for 1928 given by the British Orthopedic Association. The history of clubfoot is traced from the time of Hippocrates down through Scarpa and Little to the present, and so the author groups together in a fascinating manner the literature of the subject and this in itself is a valuable contribution.

There is however nothing new developed as to either etiology or treatment but many theories of the past of both are thoroughly discussed. The treatment of the early clubfoot will surprise many Americans as it consists of manipulation only without the fixation usually used here. One must remember however that the orthopedic surgeon of England really had as predecessor the bone setter whereas with us the orthopedic surgeon was a refined or special general surgeon becoming a specialist. As a result true manipulation as a measure for correction of deformities is more conspicuous in England than here where we have developed open operations more fully.

Ja. C. R.

STUDIES ON THE DIAGNOSIS AND NATURE OF CANCER. By Various Authors. Being Reprints of Special Articles from the "Cancer Review." Octavo of 240 pages. New York, William Wood and Company, 1930. Cloth, $4.00.

The British Empire Cancer Campaign has compiled the reprints of special articles written for the "Cancer Review" and published them in this volume of 221 pages.

Early diagnosis of the most common cancers is considered in a number of well written articles by such authorities as Handley, Kolodny, Morson, Lockhart-Mummery, Kerley, Wyard and Sir St. Clair Thomson.

The nature of cancer is discussed in (a) "The Metabolism of Tumors" by Cramer; and (b) "The Relation of Heredity to Cancer" by Cockayne. An extensive article on "Immunity to Transplantable Tumors" by Woglom, reviews 600 pertinent papers.

The book thus brings to the clinician a clear insight into the present concept of the nature of cancer, and emphasizes many practical points in the early diagnosis of neoplasms.

HARRY MANDELBAUM.

OBSTETRICS. By J. WHITRIDGE WILLIAMS. 6th enlarged and revised edition. Octavo of 1157 pages, illustrated. New York & London, D. Appleton & Company, 1930. Cloth, $10.00.

Williams' well known text book in its sixth revision is better than ever. It is an ideal text for the real student of obstetrics, the specialist anxious to increase his knowledge. It is a veritable mine of information, and yields place to no other book in the discussion of abnormal mechanisms. Pelvic deformities are exhaustively covered. It is not, however, a good textbook for the medical student, who must be drilled in essentials, before he is disturbed by critical analysis, and philosophical discussion. It is interesting to note that Williams has not yet fully accepted Henderson's views on carbon dioxide as the sole stimulant of delayed fetal respiration. The book is a masterpiece, and invaluable to the obstetrician.

C. A. G.

HISTOLOGY FOR MEDICAL STUDENTS. By H. HARTRIDGE, M.A., M.D., and F. HAYNES, M.A. Octavo of 369 pages, illustrated. New York & London, Oxford University Press, 1930. Cloth, $5.00. (Oxford Medical Publications.)

In fifteen short chapters concisely, yet fully explanatory, the authors have covered the subject of Histology in all its phases and necessary subdivisions. The various tissues and organs are described microscopically and discussed embryologically and physiologically. The definitions of new terms are simple and clear.

There are 82 well labeled colored plates, illustrating every possible detail.

The section on fixation, cutting and staining of tissues and microscopy, usually very difficult and uninteresting, is really very delightful reading.

The classification and description of connective tissue, the very important tissue, is briefly, orderly, and very intelligently compiled.

The chapter on blood and blood forming organs is very meaty. It touches the reticulo-endothelial system.

The brain and spinal cord are rigidly covered in 25 pages.

The authors should be commended for their very practical volume which should be an asset to the armamentarium of the toiling student of Histology.

NATHAN REIBSTEIN.

RIDERS OF THE PLAGUES. The story of the conquest of disease. By JAMES A. TOBEY. Octavo of 348 pages, illustrated. New York, Charles Scribner's Sons, 1930. Cloth, $3.50.

This is a very readable book, written by a Doctor of Public Health, who understands his subject thoroughly. It describes the great plagues which have devastated the human family, from the earliest historic times up to the present day, in a popular style, which presents the scientific facts in a manner readily comprehensible to lay people.

Embodied in the book are brief histories of the outstanding men who have successfully coped with these epidemics of disease and, in many instances, discovered their causes, and elaborated efficient methods for their prevention. It is a volume which should be on the waiting room table of the doctor and on the shelves of those who are interested in public health and the noble, unselfish efforts of scientists who have risked and even lost their lives for the public weal. The book is beautifully printed and well illustrated.

J. M. VAN COTT.

A PRACTICAL MEDICAL DICTIONARY. By THOMAS LATHROP STEDMAN, A.M., M.D. 11th revised edition. Octavo of 1222 pages, illustrated. New York, William Wood & Company, 1930. Cloth, $7.50.

After comparing Stedman with other medical dictionaries, the reviewer does not hesitate to say that he considers it the best.

Dr. Stedman is to be congratulated for saving the medical dictionary from the degradation of becoming the desk-book of a single group of publications. He is preserving the purity of the language of medicine by observing correct orthography established by usage, not the whim of an editor. This is the paramount duty of a lexicographer. When the editor of a medical journal deliberately chooses to misspell terms, he is within his rights. But any attempt to carry this faulty orthography into a dictionary, and thus represent it as generally accepted, is a corruption of the language of medicine and a violation of the rights of the reader.

Up-to-date in its definitions and free from bad spelling, Stedman is a dictionary upon which both physician and medical student can depend.

FREDERIC DAMRAU.

GROW THIN ON GOOD FOOD. By LUELLA E. AXTELL, M.D. 12mo. of 336 pages. New York and London, Funk & Wagnalls Co., 1930. Cloth, $2.00.

A number of fairly good books on weight-reducing have been published for the layman during the past year. This book does not depart essentially in its method of presentation from that of its predecessors.

The information is wholesome in that it conforms with accepted professional methods of treatment. The reader is warned against the uses of drugs, or against sudden losses in weight through physics or baths. Dr. Axtell recommends the free use of water, and besides offers a complete diet schedule for 21 successive days to effect a satisfactory reduction. In perusing these tempting diets the reviewer wondered whether they could actually help to reduce weight on that account. At any rate this book reflects a painstaking effort to offer something tangible for the reader, and a trial experiment by the layman could surely do no harm, especially if the cause of the obesity has been established by the practitioner.

EMANUEL KRIMSKY.

NERVOUS INDIGESTION By WALTER C ALVAREZ M D Octavo of 297 pages New York Paul B Hoeber Inc 1930 Cloth $3 75

In this book a subject of great practical interest is treated in a very satisfactory manner The ideas which most physicians have about nervous indigestion are rather vague this book will greatly clarify them It puts this difficult subject on a scientific basis It tells how emotion affects the digestive tract and what are the types of indigestion thus produced Very wise are the directions given for managing the patient which is an important part of the treatment This book should have a large appeal for the medical profession

F I CAVANAH

RECENT ADVANCES IN DISEASES OF CHILDREN By WILFRED J PEARSON D M and W G WYLLIE M D M R C P Second edition Octavo of 548 pages illustrated Philadelphia P Blakiston's Son & Co Inc 1930 Cloth $3 50

The title might suggest a review of the literature but instead the authors have given a brief practice of Pediatries somewhat general their word recent giving the practitioner some older material along with that just out

The main impression given is the general uniformity of thought in disease and standardization of method in treatment though we do think ourselves a bit ahead in our country

The authors place greater stress on diathesis than most of us are inclined to

The book is readable it is worth while for Americans to get the English point of view

One small point specially interests this reviewer The Mental Deficiency Act of 1927 recognizes Idiots Imbeciles, Feeble Minded Persons and *Moral Defectives*

W D I

LEONARDO DA VINCI The Anatomist By J PLAYFAIR McMURRICH Octavo of 265 pages Illustrated Baltimore, Williams & Wilkins Company 1930 Cloth $6 00

Leonardo da Vinci was essentially a scientist His work in Anatomy demonstrates it clearly He no doubt took to dissecting to aid him in his paintings and sculpturing nevertheless his anatomical drawings and manuscripts show that he became inquisitive in his anatomical studies far beyond his first purpose This phase of Leonardo's genius has been most ably evaluated by Prof McMurrich one of our leading modern anatomists His analysis of da Vinci's anatomical achievements is most unprejudiced based on his profound knowledge of anatomy *and of the history of anatomy It took him* ten years to create this volume of 265 pages for the Carnegie Institution It is a masterpiece most interesting instructive and entertaining He has added one more treatise to Medical History a branch of Medicine so important for the betterment of cultural Medicine

GAETANO DE YOANNA

MOTHER ALPHONSA Rose Hawthorne Lathrop By JAMES J WALSH M D Octavo of 275 pages illustrated New York Macmillan Company 1930 Cloth $2 25

A delightful book

The appealing story of Mother Alphonsa Lathrop younger daughter of Nathaniel Hawthorne who rented a little flat in New York City took incurable cancer cases into her home and mothered the work so devotedly that the little flat grew up into Rosary Hill Home Hawthorne in Westchester New York For thirty two years she labored in the cause of the poor afflicted with incurable cancer Only those were admitted for whom there was no hope Her story will never grow stale and will repay reading

C A G

HANDBOOK OF ANATOMY By JAMES K YOUNG, M D Revised by GEO W MILLER M D 7th revised edition Octavo of 460 pages illustrated Philadelphia F A Davis Company 1930 Flexible Cloth $3 75

This handbook of Anatomy is so familiar to the average *student of Medicine that it does not require any* introduction It is to be recommended as a Vade mecum to the student of anatomy and graduate in Medicine

GAETANO DE YOANNA

AN OUTLINE OF CONTRACEPTIVE METHODS for Physicians and Medical Students Exclusively By JAMES F COLLER M D Octavo of 23 pages New York City *The American Birth Control League 1930*

*Recent meetings arranged for physicians by the Amer*ican Birth Control League have proved by their large representations that the subject of contraception is one which concerns every practitioner of medicine That such an important prophylactic measure should be tabooed from discussion by our more prominent medical journals has been responsible for much misunderstanding on this matter

This booklet of 23 pages is full of valuable information and tells the practitioner in simple terms why almost every contraceptive measure with one or two exceptions is either harmful or ineffective EMANUEL KRIMSKY

THE DEVIL An Historical Critical and Medical Study By MAURICE GARÇON and JEAN VINCHON Translated by STEPHEN HUDEN GUEST from the Sixth French Edition Octavo of 288 pages New York E P Dutton and Company Inc. 1930 Cloth $3 50

The book is divided into two parts In the first which comprises more than one half the volume the authors discuss magic demonology witches witchcraft sorcerers, exorcism etc with numerous references to the Bible In quoting from a book by Sammarinus it is stated that there are seventeen symptoms which for a theologian, denote a demoniac The doctors signs enumerated by Baptiste Codroncus are also seventeen in number, the first of which is If the disease is such that the doctors cannot discover nor diagnose it

At the end of the chapter devoted to The Formation of the Christian Devil the authors state The truth is that the whole diabolic doctrine was born in the subtle brain of erudite theologians

One chapter is devoted to The Sabbath What is this Sabbath? It is the propitiatory ceremony the adoration of the Devil It is superlatively the sacrilegious festival One chapter is devoted to The Witches' Trial and another to The Modern Devil

Part two is devoted more particularly to the medical aspects of the devil and all his works The authors convey *the impression that they consider* that there is a distinct form of mental disorder which might be classed as demoniac insanity It is difficult at times to determine whether the authors are expressing their own opinions or paraphrasing the language of others They cite a number of cases and from the meagre history given some appear to be cases of hysteria some schizophrenia and occasionally a manic depressive

In the chapter headed Demoniacs and Convulsionaries the authors say The mental specialists of today class among the demonopathic states as acute mental disorders those which are due to manic fits or to melancholic anxiety to dream—delusions of confusional states among disorders of slower evolution must be classed delusions of interpretation and of imagination without hallucination and hallucinatory delusions where the mystic duality intervenes the eternal conflict between God and the Devil

Under therapy they advocate the cooperation of priest and physician and say 'It is much to be desired that the hope of Frederick of Spee and Jean Wier will *not* remain unfulfilled *and* the association of religious and lay treatment may achieve the relief of those who without it would continue in the midst of our modern life to suffer the torments of the Possessed of the Middle Ages

I O TRACY

OUR NEIGHBORS

LEGISLATIVE PROCEDURE IN TEXAS

The February number of the *Texas State Journal of Medicine* begins with the following editorial describing the legislative methods at work in Texas, which are in contrast with the procedure in New York:

"The whole procedure of the legislature has been changed. The first thirty-day period of the session is supposed to be devoted entirely to the introduction of bills and the consideration of emergency measures. During the next thirty-day period nothing but committee hearings will be on the regular docket. Debate and final determination will be reserved for the last sixty days. That makes a four-months' session and, carried out as intended, will give a much more deliberative session. It is not being carried out exactly as intended, but those legislators dealing with controversial subjects are, for the most part, holding back their measures so as to accord exactly and beyond a doubt with the aforesaid constitutional amendment. Under this amendment, as a matter of fact, by a four-fifths vote the procedure may be interfered with. The difference of opinion among authorities lies in the decision as to whether this provision has reference to individual measures or whether it may be made a blanket affair.

"Bills are not printed until after committees have passed upon them and reported them back to their respective bodies. For that reason it is a difficult matter to learn at this stage of the proceedings just what any measure seeks to do, beyond the information found in its caption, and that is not always illuminating.

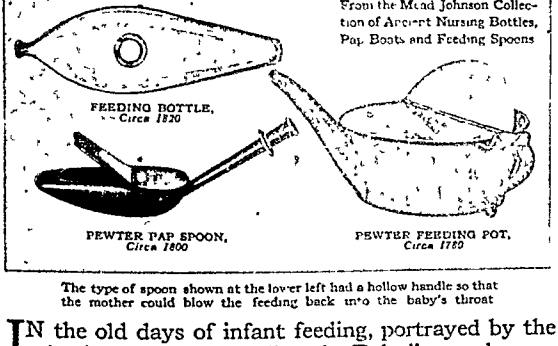
"Our two measures, namely the annual registration bill and the bill amending the Medical Practice Act, were both introduced early. The former is known as House Bill No. 6 and the latter as House Bill No. 7. An effort will be made to have the committee pass on these two bills on the first day of the second thirty-day period of the session. They will then have priority on the calendar of the House, in accordance with their early number. This means that we must be on our toes if we expect to bring about the enactment into law of these two essential measures. They have been introduced only in the House. Our friends in the legislature saw no need of bothering the Senate with them until the House had finished. The Senate passed these bills several times during the several sessions of the last legislature"

The editorial then discusses some of the bills especially the chiropractic as follows:

"The chiropractic bill differs in no important particular from that which has gone before. It seeks to pattern after the Medical Practice Act. It is quite clear that many of its provisions are for effect on the legislature and intended merely as talking points. The big idea is to get the sanction of the State, both as a boost for chiropractic and as a protection for those practitioners of this cult who may receive the cloak from the Elijahs at the present time on the job.

"The subjects covered by the examination provided for in the measure are as follows: Anatomy, physiology, symptomatology, chiropractic principles, technic and diagnosis, neurology, spinal orthopody and vertebral palpation, and chiropractic adjusting as taught by chiropractic schools and colleges, chiropractic jurisprudence and public health service. We are just wondering whether the examination in anatomy will call for a knowledge of those hypothetical nerves which carome around over the body from the spinal cord to the eye and nose, and regions thereabout, in order to enable the chiropractor to relieve blindness and the like by adjusting the spine. And we also wonder what chiropractic public health service is."

PUBLIC RELATIONS IN INDIANA



The Indiana State Medical Association has a special committee called the Liaison Committee whose duties are those of the Public Relations Committee of New York State in that it forms contact with organizations outside of the medical profession. The President of the State Association, Dr. A. B. Graham, of Indianapolis, writing in the February Journal of the Indiana State Medical Association says:

"The Indiana State Medical Association has a liaison committee the chairman of which is our president-elect. This liaison committee has been and is now doing a splendid work. Recently its chairman was in session with the chairmen of committees appointed by the following associations:

The Indiana Hospital Association.

(*Continued on page* 380—*adv. xii*)

CEREALS THEN — AND NOW:

The type of spoon shown at the lower left had a hollow handle so that the mother could blow the feeding back into the baby's throat

IN the old days of infant feeding, portrayed by the classic painting, "Feeding the Baby", cereals were "pap" and were fed to babies with a "pap spoon" or with a "pap boat" from a "feeding pot."

The pap was usually made from bread crumbs boiled in water, and supplemented the frequent breast feedings which were continued into the child's second year.

Fortunately for the babies of those pre-vitamin and pre-mineral deficiency times, whatever elements were lacking in this crude cereal were made up by the generous supply of the mother's breast milk. So that these babies lived neither by bread alone, nor by milk alone. In their own way, mothers had learned that neither cereal nor milk is a perfect food.

Nowadays, babies are not breast fed to the same extent nor for so long a period as were the babies of those days. They are early placed on cow's milk which, among other elements, is lacking in iron, copper and in the antineuritic vitamin B.

For a century and a half there has been no outstanding improvement in cereals from a nutritional viewpoint. High in starch, low in protein, deficient in calcium and other minerals, scarce in vitamins (especially G), each of the cereal grains remains today what it was then.

To make matters worse, "the highly milled products, particularly of white flour, constitute another avenue of escape of vitamin B in the present diet."*

Mead's Cereal, now available to the medical profession, draws its nutritional and palatable qualities from a carefully tested mixture of farina, oat meal and corn meal. From the added wheat embryo, it derives iron and vitamins A, B, E and G. Yeast furnishes copper, as well as iron; also vitamins B and G, while powdered bone richly supplies calcium and phosphorus, two essential factors lacking in ordinary cereals. By the addition of alfalfa, both iron and vitamin A are contributed and the flavor notably improved.

Mead's Cereal, therefore, represents this significant step in the development of cereal nutrition: Derived from natural sources, it contains nine minerals and four vitamins in substantial amounts, together with protein, fat, carbohydrate and calories.

Mead's Cereal was devised,† after long study, in the Research Laboratories of the Hospital for Sick Children and the Department of Pediatrics, University of Toronto, and is regularly tested by the Pediatric Research Foundation.

Just as vitamin C is prescribed in a specific vehicle like orange juice, and just as vitamin D is prescribed in a specific vehicle like viosterol or cod liver oil, so it is hoped that Mead's Cereal will be prescribed for all other vitamins and for its rich supply of essential minerals‡ as an important supplement to the diet of the young baby and the adolescent child.

Please send for a package of Mead's Cereal for use in your household.

The Catholic Hospital Association of Indiana.
The Indiana State Nurses' Association.
The Indiana State Dental Association.
The Indiana Pharmaceutical Association.
The Indiana Tuberculosis Association.

"The purpose of this session was to develop a spirit of mutual interest in the mutual problems of these naturally allied interests. The chairman of our liaison committee reports that the idea went over big. However, he stressed the very important point that these committee chairmen in turn must now sell the idea to their respective associations which they represented.

"Any organization that is sincere in its efforts in relieving human suffering and misery within the boundaries of our state is entitled to and deserving of the cooperation of our Association. The report of the chairman of our liaison committee is in sympathy with the ideas I have expressed. It is now absolutely essential that these ideas be sold to our members. A concerted policy on the part of all our members must be obtained before successful results can be attained."

Dr. Graham describes the assistance and endorsement given to the State Tuberculosis Association and continues:

"This action on the part of your Executive Committee will in all probability be regarded by some of our members as just another step toward state medicine. As to just what this much discussed and supposedly threatening bugaboo, state medicine, is, I do not know. I may perhaps have something to say regarding this subject in the near future. At the present time the mention of the term state medicine does not cause me any undue anxiety. I am very thankful for the possession of sufficient optimism as to make me opine that state medicine and a concerted policy on the part of all or even a majority of the members of the Indiana State Medical Association are not compatible. If perchance state medicine should overtake us, it can only imply that very unfortunately the medical profession failed in the performance of its assigned duties, and the censure for this disaster must very properly be placed at its own door. State medicine is a possibility—yes, a probability—but not with a concerted policy on the part of members of the Indiana State Medical Association."

PHYSICIANS' CARDS IN THE TEXAS JOURNAL

The medical journals of several Western States publish the professional cards of physicians with the full approval of their State Societies. The February issue of the *Texas State*

(Continued on page 381—adv. xiii)

(Continued from page 380—advertising)

Journal of Medicine is an example of a State journal, giving publicity to those physicians who are willing to pay for the advertising space. That journal carries eleven pages of advertisements of doctors, mostly specialists listing 123 advertisers.

The number of partnerships is striking. The advertising cards listing two doctors in partnership number 30, those with three partners 9, with four partners, 2.

Associations consisting of more than three physicians are usually listed as clinics. Nine such clinics are listed, containing 88 doctor members.

Altogether the names of 267 doctors are listed in the advertisements, while 34 spaces are marked 'for sale, $2 per issue.'

It may be interesting to know what State Societies sanction the insertion of physicians cards in their Journals. There are 32 official state journals organs of 43 State Medical Societies. The Journals publishing physicians cards in their advertising departments number 14 as follows:

Arkansas, Indiana, Iowa, Kansas, Kentucky, Michigan, Nebraska, New Orleans Medical & Surgical Journal (Louisiana and Mississippi), Northwest Medicine (Oregon, Washington, Idaho, Montana), Oklahoma, Rhode Island, Tennessee, Texas, West Virginia.

This summary is not a criticism in any sense of the word. The members of the Medical Society of the State of New York do not wish to list physicians in the advertising pages of their Journal, but they are willing that the members of other State Societies should do so.

MEDICAL MOVIES IN INDIANA

The February issue of the Journal of the Indiana State Medical Association contains an article by Dr. W. D. Little, evidently in comment on three original films which were shown at the meeting of the State Society. The pictures were described as follows:

"The first picture is part of the film which Doctor Gilman took to the State Medical meeting in Fort Wayne. He was to show it twice and he showed it twelve times—ten times by request. It was made at the City Hospital through the courtesy of Doctor Doeppers. You may feel inclined to criticize the technique because there is a fly buzzing around the patient during the cisternal puncture but I feel it serves a good purpose, because it shows the patient was more concerned with the fly than the puncture. It was made out doors in August on the City Hospital roof.

"The second picture is a combined median and ulnar nerve lesion in a little boy who came to the

The Follow-Thru Of Your Instructions

THE physician who prescribes exercise for his patients is generally too busy to follow thru his instructions to see whether the prescription is being carried out—or neglected.
The physician who takes the extra precaution of sending a client to McGovern's Gymnasium for exercise and re-building has the assurance that his "exercise" prescription is being carried out to the letter, and that he can follow the progress of his patient by regular reports.
A work-out at McGovern's will show you why so many physicians send patients here. We'll be glad to send you a guest card.

Riley Hospital. Combined injury of the median and ulnar nerve is not uncommon, but such injuries usually occur as a part of extensive and complicated wounds which damage a great deal of the hand and wrist. In this boy the nerve injuries were the only things of importance. No tendons, arteries or other structures were cut.

"The third picture is one of Doctor Garceau's orthopedic patients which shows that motion pictures make a better record of many orthopedic patients than any other record we can have. We do not have a follow-up on this boy, but we will have pictures at various times to show his progress during all stages of treatment."

Dr. Little makes the following excellent comments on the value of medical movies:

"A great many amateur photographers have attempted to make pictures of operations, but even when panchromatic film has been used, there is not enough differentiation between blood and muscle and fat and the other structures to make them very valuable when projected on a screen. It is not possible to distinguish the different structures very clearly, and most films of this type have been a disappointment. Some orthopedic operations may be well shown, especially if animated drawings are used in connection. The chief use, it seems to me, for motion pictures in medicine is first to make a better record of some patients than can be made in any other way; the second, it will allow the accumulation of a vast variety of cases with the same deformity."

EXHIBITS IN ILLINOIS

The annual meeting of the Illinois State Medical Society will be held in East St. Louis, May 5-7 and will emphasize its exhibits, both scientific and commercial. The *Illinois Medical Journal* of February comments editorially on the exhibits, as follows:

"One of the interesting features of all modern medical meetings is the exhibits. At East St. Louis, we will have one of the finest exhibition halls in the state of Illinois. The spaces are all unusually large, and there will be uniform booth set-ups all ready to be occupied by the exhibitors.

"There will be an unusually large number of fine scientific exhibits this year, and any member of the Illinois State Medical Society who has something that he would like to exhibit, that is free from all advertising, should make application at once with the Secretary, stating the nature of the exhibit, naming the features of general interest, and proper space for same will be allocated.

"Only commercial exhibits that are on the approved list of the American Medical Association will be shown at the meeting. Arrangements are being made whereby our exhibitors will be well cared for at the meeting. Every exhibit space is

(Continued on page 383—xv)

(Continued from page 382—adv xiv)

unusually adapted to suit the convenience of our exhibitors, and each is a desirable space, regardless of price.

"A synopsis of each exhibit will be given in two issues of the *Illinois Medical Journal* before the meeting, and will also be printed in the official program of the meeting.

"The Illinois State Medical Society has an unusual appeal this year to prospective exhibitors, and the attendance should be unusually large. The St. Louis Medical Society, and the Missouri State Medical Association have given every assurance that they will aid our Society in making the meeting a successful one, and will give it much publicity on the West Side of the river.

"It is hoped that all members of the Illinois State Medical Society will favor our exhibitors, and make them feel that it is worth the expense and effort to have exhibits at the Annual Meeting of the Illinois State Medical Society."

LICENSURE IN CALIFORNIA

The February number of *California and Western Medicine* contains an editorial describing vividly the extent of medical cultism in California, and says:

"In the December issue of *California and Western Medicine*, page 915, was printed one of the monthly reports of the California Department of Professional Standards, in which department under Division No. 1, the Board of Medical Examiners has a place. Under Division No 2, the figures showing the number of licentiates who in the last decade have been granted licenses as 'doctors' of the healing art of one particular cult were given. Almost three thousand of such have been licensed in California in the last ten years!

"In some of the Sunday Metropolitan newspapers of California may be found the alluring and come-on advertisements of some of the schools of that cult. From time to time illustrated single, double and triple column reading notices have appeared in the news columns of newspapers, playing up 'perfect infant,' 'most beautiful female back,' and what-not-side-shows held at the annual or other sessions of the societies of such cults. To these 'beautiful female back' shows the members of the laity are invited.

"In another cultist group, prize contest announcements were sent out to the high schools, inviting all students to participate. The daily press recurrently made mention of the contest, and much free or paid for publicity was thus secured for that cult. The award in one such contest, if our memory serves us well, was one year's free tuition in a school of the cult. This award was granted to the high school student who gave the best reasons why a young man

should choose as his life work the practice the profession of that particular cult.

"One of these cultist groups has licensed abo 3,000 practitioners of that cult in California the last ten years or so. That is a large numb for even so large a state as California to assim late, digest and take unto itself. The law brin ing into existence the examining board of th cult contains many defects, but was passed as a initiative act, and therefore can only be amend by the people. Yet that law, sanctioned sever years ago by vote of the electors of Californi makes it obligatory for the examining board c that particular cult to accept the diplomas c practically all chartered schools of that cul without regard to the quantity or quality of th courses given. The language is so loose th diplomas of any kind of a state-chartered scho of that cult must be accepted. The examinir board of that cult cannot step in and inspect th schools in an effort to maintain the standar which even its own members favor. And th in California, the sixth state in the Union, wi its 1930 United States census population 5,672,009 persons. Truly a remarkable state affairs.

"Nor is the above citation all. For in one the well-known newspapers of California, a pu lication with advertising figures comparing favo ably with those of papers of cities such as Ne York and Chicago, there is a so-called heal column in one of its magazine sections flank by and including a surprising number of wh seem to be misleading advertisements. This pa ticular health column for the last several decad has been one of the big revenue producers that portion of this particular newspaper, a the present editor of its columns is said to mai tain a suite of offices covering almost the ent floor of one of the large buildings in that pa ticular city, where he supposedly practices t healing art according to the tenets of his cult.

"What can be done about conditions such have been noted? The answer ofttimes must b not very much, for the State of California, on having granted legal licenses to practice the he ing art, cannot recall such licenses except for leg causes; and the electors having voted a deplo able set of minimum standards for licensure certain cults, only the people by again registeri their votes in favor thereof can raise or bett those deplorable standards.

"However, from the standpoint of preventi medicine, the regular or non-sectarian professi does owe it to itself and to the public to enlight the laity concerning health and concerning d ease prevention. Such publicity the professi has given in the past through publication of jou nals on hygiene and of miscellaneous pape Are any more effective methods available?"

FEE SPLITTING IN PENNSYLVANIA

A new form of fee splitting is recorded in the February number of the *Pennsylvania Medical Journal*, which says.

"We have received 'the last word' in the commercialization of male babies. As a practitioner of medicine the writer received in the mail a printed folded-leaf pamphlet, and a printed circular letter from a Philadelphia rabbi. The leaflet is printed with blue ink, possibly in keeping with this appropriate color scheme for boy babies."

Then follows a copy of the leaflet which contains testimonials from seven physicians, all from New Jersey, and also those of three laymen, praising the rabbi's skill in doing circumcisions. The leaflet also contains the following letter from the rabbi, who signs himself as a surgeon mohel:

"I am addressing these lines to you with the hope of gaining your cooperation in recommending me as a Surgeon Mohel to confinement cases you are attending where there is the birth of a son to be circumcised.

"I am a Surgeon Mohel, having many years of practical experience; having circumcised hundreds of male babies, and in possession of many references of the parents whose children I have circumcised, as well as physicians.

"I use every modern, hygienic precaution and being a man in the prime of life I am fast, causing practically no pain during the circumcision of the newborn baby

"I will gladly reward you for your kindness and will pay you for any circumcision I will perform through your recommendation. I will not use your name in any case without your consent and I can assure you that you will never have any cause to regret your recommending me to confinement cases you attend.

"P. S. The fee for your part will be 40 per cent. Your only obligation is to give me the name and address of your confinement case."

The editorial ends:

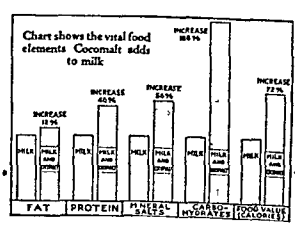
"From an investigation we find that many of the physicians in Philadelphia have not received this correspondence, and that two hospitals have refused him admission based upon complaints filed by certain members of the staff of both institutions who had received this letter.

"We understand this rabbi is very poor and has resorted to the procedure herewith detailed to increase his income. We sympathize with his poverty, but must unqualifiedly condemn his method to relieve it. His correspondence is a direct insult to the medical profession, and his fellow rabbis."

. . . whenever milk is an important part of the diet

Cocomalt not only renders it more palatable but increases its food value over 70%

COCOMALT is a delicious, high-caloric food—ideal for convalescents, expectant and nursing mothers and undernourished children.



Not only does Cocomalt make milk a tempting chocolate flavor drink; *it actually increases its food value* 70%—adding 46% more protein, 56% more mineral salts (Lime and Phosphorus), 188% more carbohydrates.

Laboratory tests show that Cocomalt contains Vitamins A, B complex and D. Vitamin D is present in sufficient quantity to make a definite contribution to the anti-rachitic potency of the child's diet.

Cocomalt is available at grocery and drug stores in ½ lb., 1 lb. and 5 lb. hospital can.

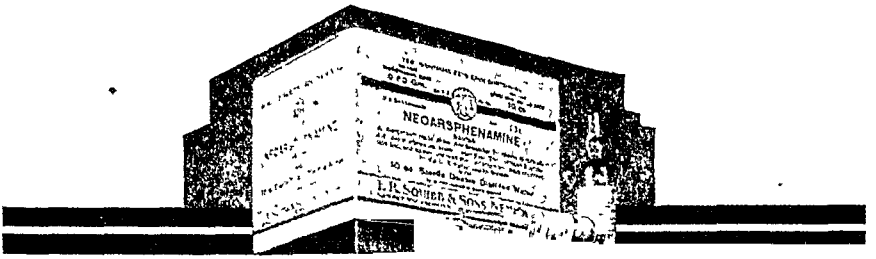
COMMITTEE ON PUBLICATION

BASIC SCIENCE LAW IN ARKANSAS

The Basic Science Law of Arkansas became a law on March 14, 1929, and is now in operation. It consists of twenty-one paragraphs, but its essential features are found in the first three which are printed in the February issue of the Journal of the Arkansas Medical Society as follows:

Section 1. Basic Science certificate required. No person shall be eligible for examination or permitted to take an examination for a license to practice the healing art or any branch thereof, or granted any such license, unless he has presented to the licensing board or officer empowered to issue such a license, a certificate of ability in anatomy, physiology, chemistry, bacteriology, and pathology (hereinafter referred to as the basic sciences), issued by the State Board of Examiners in the basic sciences.



Section 2. The Healing Art Defined. For the purposes of this Act, any license authorizing the licentiate to offer or undertake to diagnose, treat, operate on, or prescribe for any human pain, injury, disease, deformity, or physical or mental condition is a license to practice the healing art.

Section 3. Board of Examiners in the Basic Sciences. The Board of Examiners in the basic sciences shall consist of five persons to be appointed by the Governor, and the Superintendent of Public Instruction who shall be a member ex-officio. Every member shall serve until his successor is appointed and qualified. The members of the Board shall be selected because of their knowledge of the basic sciences aforesaid. No member of the Board shall be actively engaged in the practice of the healing art or any branch thereof. No member of the faculty of any medical school shall be eligible to appointment as a member of said Board. The members shall be appointed one for two years, one for three years, one for four years, and one for five years and one for six years from the date of their respective appointments. Upon the expiration of the terms of any member, the Governor shall fill the vacancy by appointment for a term of six years. Upon the death, resignation or removal of any member, the Governor shall fill the vacancy by appointment for the unexpired term. The Superintendent of Public Instruction shall supervise all examinations conducted by the Board, and the office of said Board shall be in the office of said Superintendent."

BIBLIOGRAPHIES—AN INDIANA OPINION

Some State Medical Journals refuse to publish bibliographies on the ground that they have little to do with the article. The policy of the NEW YORK STATE JOURNAL OF MEDICINE is in accord with that of *Northwest Medicine* as stated in the

(*Continued on page 388—adv. xx*)

"Low toxicity."

sometimes these are dangerous words

Authorities on syphilology are emphasizing the fact that laying too much stress upon the flash solubility and low toxicity and too little upon the curative activity in the manufacture of Neoarsphenamine is a very dangerous thing in the treatment of luetic cases.

One writer believes that a high incidence of tertiary syphilis will be observed in later years because of the lack of spirocheticidal activity in some brands of Neoarsphenamine.

The production of Neoarsphenamine Squibb Improved is rigidly controlled to yield a product of high therapeutic (spirocheticidal) activity and at the same time to provide an ample margin of safety from the standpoint of toxicity. Neoarsphenamine Squibb Improved is prepared solely from the therapeutic viewpoint. Of course it is readily soluble, but its uniformity and parasiticidal activity plus a wide margin of safety are the features of greatest interest to the physician.

Neoarsphenamine Squibb Improved is distributed in ampuls containing 0.15, 0.3, 0.45, 0.6, 0.75, 0.9, 3.0, and 4.5 Gm.

For an interesting booklet giving complete information about Neoarsphenamine Squibb Improved, write to the Professional Service Dept., 745 Fifth Avenue, New York City.

A characteristic of Mead's Powdered Lactic Acid Milk No. 1 (containing Dextri-Maltose) is the finely divided soft curd which never clogs the nipple. In a few moments, any mother can carry out the simple procedure required without error — a saving in time to her and an assurance to the physician that the feedings are correctly prepared. This product never curdles; it is always ready, and quickly reliquefied. No ice is necessary to keep the powder. It is convenient while traveling. Samples and literature on request. Mead Johnson & Company, Evansville, Indiana, U.S.A.

(*Continued from page* 385—*adv. xviii*)

first editorial in the February number which says:—

"Whenever one writes a paper on a given medical topic, he must of necessity consult certain books and medical journals, from which a large proportion of his information will be obtained. If he wishes the paper to present an air of authority, this will be fostered by references to the texts which he has consulted in its preparation. It is customary to publish these references in the form of bibliography at the end of a paper or as foot-notes to each page in which they appear. The latter plan is commonly considered preferable as it offers convenience of reference and the notes are more likely to be consulted by the reader.

"Sometimes an author attaches to his paper a list of references of considerable length in addition to those mentioned in the text. It is not considered desirable to include these, as usually they are not intimately connected with the substance of the paper and occupy space that might be more profitably employed. The most extensive collection of references will be found in the French thesis, which every graduate from the University of Paris must present before obtaining his degree. Such a paper may occupy months or years in preparation. When completed it will list every publication which has appeared in any language on the subject of the paper. Naturally anything approaching this in completeness is out of place in connection with a paper published in a monthly medical journal. It is desired to emphasize the fact that suitable references elucidating the text are of value in connection with the writing of any paper. They should include the names of authors, titles of papers and the journal or book in which they have been published."

POPULAR MEDICAL EDUCATION IN ILLINOIS

The *Illinois Medical Journal* for February contains the following summary of the work of the Education Committee of the State Society for January:

Health talks, 35 in number, were given before Women's Clubs, Church Groups, Farmers' Institutes, Young Mothers' Clubs, Parent Teacher Associations, Y. M. C. A.'s. Among the subjects presented were—Religion and Health, Cancer, Periodic Health Examinations, Sex Hygiene, Child Psychology, Mental Hygiene, Communicable Diseases, Child Health, Early Detection and Correction of Defects, Animal Experimentation, Sheppard Towner Legislation.

Radio talks, 35 in number were given, from WGN and WJJD.

Scientific papers scheduled: 9, before as many county medical societies.

Films: A new film on carbon monoxide, loaned by the Bureau of Mines, Pittsburgh, Pa., was secured to be shown in factories in Chicago.

Press service: 355 regular press releases.

Health education: 9 articles prepared.

MENTAL HYGIENE IN PENNSYLVANIA

The February number of *The Pennsylvania Medical Journal* has the following announcement:

"The outlined activities for the Medical Hygiene Committee of the Medical Society of the State of Pennsylvania for the ensuing year reflect the committee's desire to be of extreme help to the physicians, members of the auxiliary, and the public at large.

"While the activities seem far-reaching, the committee feels with its organization of psychiatrists in the eastern, central, and western sections of the State, by the close of the year its efforts will have met with just rewards. The committee, however, can do nothing without the support and cooperation of the component county medical societies and the individual physician

"A brief abstract of the program should be interesting to the readers of the Journal, which is as follows: (1) Promoting a mental hygiene day in each county society; (2) a similar day for each woman's auxiliary; (3) providing a speaker on mental hygiene before the next annual session; (4) cooperating with program committees of sections in arranging symposia, etc.; (5) promoting a speaker's bureau on mental hygiene for nonmedical organizations; (6) arranging for clinics at mental hospitals for county societies; (7) stimulating a greater interest in psychiatry in medical education; (8) urging the cooperation of general hospitals in treating borderline cases; (9) arousing the physician's interest in maintenance needs of our mental hospitals and the need of a psychiatric hospital; (10) presenting an editorial monthly to the State Journal on mental hygiene in some of its phases."

LEGISLATION IN OHIO

The problems of medical legislation are the same in all the States. The following editorial in the February issue of the *Ohio State Medical Journal* would apply equally well to New York State:

"Representatives of the cultists and faddists have been much in evidence at all sessions of the General Assembly to date and it is no secret that they have already obtained the promises of too many members of the Legislature to support the vicious and destructive proposals that they hope to have enacted. On the opening day of the General Assembly the halls of both houses were circularized by the anti-vaccinationists and anti-vivisectionists with their usual type of false, ignorant and destructive propaganda literature, followed later by propaganda by chiropractors, christian scientists and other cults.

"The selfish and ill-advised demands of these groups are certain to add to the confusion and pressure of the present session of the law-making body, which is already confronted with the important task of studying and enacting into law an unusually large number of vital, necessary and constructive measures.

"The present session of the General Assembly challenges the alertness and active interest of the medical profession and organized medicine of Ohio.

"Of course, the Policy Committee and the state headquarters of the State Association, as in the past, will closely watch all legislation and will communicate developments and suggestions to the legislative chairman in each county medical society and academy."

AUTOMOBILE INSURANCE IN GEORGIA

The February issue of the Journal of the Medical Association of Georgia records the following action taken by the Ware County Medical Society:

"*Whereas,* The number of automobile accidents on the highways is showing an alarming increase, and

"*Whereas,* The increasing number of injured persons is taxing both the medical profession and hospital facilities to the utmost to render necessary treatment, and

"*Whereas,* The persons injured are frequently irresponsible, and without means to pay either for medical attention or hospital services, thereby placing an unfair burden upon them; therefore be it

"Resolved: That this Society petition our local Legislators to introduce some comprehensive measure making the carrying of liability insurance compulsory in this State by all individuals who secure a license from the State to operate any motor vehicle within its boundaries, and be it further

"Resolved: That copies of this resolution be sent to the editor of the Journal, to the Committee on Public Policy and Legislation, and to all the County Societies with the request that they endorse it, and petition their respective legislators to aid in securing such an act."

HELP TO MEDICAL WRITERS IN IOWA

The January number of the Journal of the Iowa State Medical Society announces that the Society will assist its members in writing articles, and says:

"Through the personnel of the editor's office of this Journal, suggestions and assistance may be obtained in preparing medical papers. We are glad to cooperate with any member of our Society in the preparation of scientific papers, whether for use in the Journal of the Iowa State Medical Society or not, and will undertake such service as editing, proof-reading, compilation of bibliographies, tracing of references, preparation of cuts and typing of manuscripts. This service will be rendered to our readers at nominal expense and by persons whom we can recommend for accuracy and training in this particular work.

"Finally, I would offer two suggestions for the guidance of every medical author. One, know what you have to say. Two, say it and stop."

Vol. 31, No. 7 NEW YORK, N. Y. April 1, 1931

PERFORATED ULCERS OF THE STOMACH AND DUODENUM*

By MANDEL WEINSTEIN, M.D. and JOHN P. McHUGH, M.D., LONG ISLAND CITY, N. Y.
A Review of Fifty Cases With Particular Emphasis Upon the Current Methods of Treatment.
From the Surgical Service of St. John's Hospital, Long Island City, New York.

JUDGING from the vast literature on the subject, widely diverging views prevail as to the proper methods of treating perforated peptic ulcers. All agree that the earlier operative measures are instituted from the time of perforation, the greater will be the number of recoveries. But the procedure varies from the more radical gastric resections at the time of perforation, to simple closure of the ulcerated opening.

We believe that the time-proven principles of surgery also find their application here: an emergency surgical operation should occupy as little time as possible together with a minimum amount of operative trauma. If upon the recovery of the patient, carefully applied medical treatment fails to make the patient comfortable, and to arrest the pathology, further surgery can always be resorted to.

Herewith are recorded all the cases of acute ulcers of the stomach and duodenum admitted to St. John's Long Island City Hospital during the past two and a half years—an even fifty in number: Our youngest patient was 19 years old, our oldest 72. Read (10) records two cases of 18 years, and one of 76 years. Dunbar in a review of 387 cases of perforated ulcers from the Glasgow (Scotland) Royal Infirmary, reported as his youngest patient a boy, 12 years of age. As a general rule perforation takes place between the ages of 20 and 40, which interval of life in our series comprised 50% of the total number. The average perforated ulcer patient is in a lowered state of health. He is undernourished and complains of indigestion symptoms. Upon interrogation, several said they had observed tarry stools. Only six patients (12%) of the total number denied this past history. However, it is well known, Huddy (4), that a negative history is many times the result of the patient's indisposition to answer questions accurately, because of the gravity of the illness. Sherren (11) had a similar experience, for he found that in 218 cases of perforated duodenal ulcers treated at the London Hospital, only six had no history of indigestion; and the same was true in 248 cases of perforated gastric ulcer. Walton (12) is of the opinion that every gastrc, and the great majority of duodenal ulcers which perforate are of the chronic type. To McGreery (7) induration indicated chronicity of the ulcer, and this was present in all their cases.

Pathology—All perforations are minute in the beginning and rapidly enlarge. In the earlier stages, flakes of lymph may be seen on the surface of the stomach and duodenum. Ninety percent of perforated ulcers are situated on the anterior wall. The perforation is recognized as a round, punched out opening a little less than 1 cm in diameter. The edges of the opening are always indurated and the surrounding peritoneal surface shows recent changes of inflammation.

It is impossible to determine from the appearance of the opening whether it be a perforation of a chronic or an acute ulcer; for in every case there is induration, and one cannot decide whether this is due to an edema, or a fibrosis.

As soon as the abdomen is opened, gas or a little thin, clear, or turbid fluid will escape. Both gas and fluid are without odor, and when the fluid is examined it is found n many cases to be sterile. The amount of gas and fluid will depend upon the length of time that has elapsed since the perforation. If less than six hours, there will be little or no gas and the fluid will be mucoid, clear or nearly so.

Occasionally, more than one ulcer is present. One patient in this series had a perforation of a duodenal ulcer which was sutured at the time of operation. At autopsy, another ulcer 3 cm in diameter was revealed situated posteriorly. The posterior ulcer was covered by a loose layer of plastic exudate and evidently admitted no duodenal content into the peritoneal cavity.

* Read at a Stated Meeting of the Medical Society of the County of Queens, on January 27, 1931.

Most of the perforations take place in or about the pyloric vein, but with the acute inflammatory reaction, it is difficult to determine which side the ulcer is on. In fact, according to Bevan (1) there is little reason for differentiation between gastric and duodenal ulcer in this region, because of the anatomy and physiology: (that is) the duodenal cap or bulb is not a part of the duodenum but a part of the stomach; its blood supply and innervation are the same as those of the stomach and not of the duodenum; and the mucous membrane is separated from the mucous membrane of the duodenum at the line of the sphincter of the duodenal bulb or cap.

Symptoms—Moynihan's (8) classical pathological history, narrated almost twenty-five years ago still applies in making the diagnosis of perforated peptic ulcer. The condition is most frequently mistaken for acute appendicitis. One reason why some medical men fail to recognize perforated ulcers is because in the early stages the pulse rate is practically normal, Deaver (2). Collapse is a variable occurrence and should not always be expected. The temperature in the early stages is normal, sub-normal or but slightly elevated. Even in the later stages it is a mistake to expect high temperature, although it may occasionally occur. However, the history of acute agonizing pain, in a restless patient tossing from side to side, knees and thighs flexed, boardlike abdominal rigidity, shallow respirations, and the appearance of being seriously ill—confirms the diagnosis.

Anesthesia—Ten of the fifty patients (20%) in this series were operated upon under subarachnoid block (spinal) anesthesia. Neocaine .12 gms. was used and the technique employed was that introduced into this country by Gaston Labat (6). Nine of these ten patients recovered. The only fatality occurred in an extremely emaciated old lady, who had sustained her ulcer perforation 22 hours before reaching the operating room. Moreover, a recovery is recorded in a patient whose interval from the time of perforation to operation is accurately placed at 29 hours.

The critical state of the perforated peptic ulcer patient is no contraindication to spinal anesthesia. On the contrary, as indicated by Koster (5) spinal anesthesia effectively prevents shock. The blockade of shocking impulses coming from the operative field has a distinct beneficial influence on the central nervous system and is at least as efficacious in producing the anociassociation of Crile as local infiltration. Almost immediately following the injection, the patient who was restless, moaning with pain, and in many instances in a state of collapse, suddenly becomes quietly subdued and free from pain. He leaves the operating table feeling much better, and usually demonstrates a slowly climbing blood pressure. The greatest drop in blood pressure in our series was from 150 systolic and 70 diastolic to 40 systolic and 10 diastolic—a fall of 110 mm. of mercury.

BLOOD PRESSURE VARIATIONS DURING SPINAL ANESTHESIA—Ten Cases:

Preoperative		*Lowest Readings*	
Systolic	Diastolic	Systolic	Diastolic
120	64	90	60
106	66	106	66
160	80	48	36
120	80	75	60
50	0	45	0
102	64	106	70
110	70	60	0
150	70	40	10
142	110	60	40
110	70	90	55

Spinal anesthesia fulfils all the requirements of an ideal anesthetic for these cases. The complete absence of intestinal distention eliminates the use of laparotomy pads. Because of the considerable muscular relaxation and excellent exposure, recognition of the perforated ulcer area is extremely simplified. The completed operation of simple closure should therefore occupy not more than 25 minutes.

Inhalation anesthetics are best given to patients who have been prepared for operation. Such anesthetics administered without satisfactory preparation in emergency surgery, complicate operative procedures and may lead to grave postoperative sequelae. Spinal anesthesia may be performed without these drawbacks. This is particularly true in emergencies complicated by upper respiratory infections.

Postoperative headaches which occur in about 15% of our cases, we find are instantly relieved by the intravenous injection of one ampoule of caffeine and sodium benzoate, administered slowly.

Methods of Treatment—Of the 50 cases herewith recorded, 46 (92%) were treated by simple closure of the perforation. In the majority of cases omentum was tacked over the suture line for reinforcement. In only one case was an immediate gastro-enterostomy performed at the time of closure. This procedure was added because suture of the large perforation narrowed the duodenal lumen considerably. Another patient, who two years after simple closure presented symptoms of duodenal obstruction, received a gastro-enterostomy. Two of these cases were treated by simple drainage.

The question arises, is simple closure of the perforation sufficient surgery for these unfortunate patients? All agree that where the closure entails an appreciable encroachment onto the lumen of the viscus, an immediate gastro-enterostomy is indicated. But aside from this evident indication, the surgeons' opinions are many, and the operative procedures numerous.

We learned from the follow-up that many patients have felt exceedingly well after simple

closure Those who adopted a restricted diet enjoyed freedom from symptoms Their roentgenograms showed no gastric retention of the contrast media after six hours and little or no pathology about the site of the operation On the other hand, patients who did not submit to post operative medical treatment, suffered the same fate as ulcer patients who had never perforated, namely, pain, indigestion symptoms, etc Our youngest patient, 19 years of age, continued medical treatment for five months Since then he has disregarded all medical advice with the result that he presents at this time progression of ulcer pathology His roentgenograms show a small stomach, with 50% retention after six hours A gastro enterostomy or more radical surgery is indicated to relieve his symptoms

McCreery (7) also believes that a cure can be obtained early in these cases of simple suture if proper postoperative medical treatment is instituted He advances the argument that gastro enterostomy prolongs the operation 20 minutes and opens up to infection the clean lesser peritoneal cavity However subsequent gastro enterostomies occasionally had to be performed upon his patients because of recurrence of symptoms Walton (12) believes that simple suture combined with immediate gastro enterostomy may also be followed by recurrence of ulcer symptoms Besides, gastro jejunal ulcer is still a complication to be considered Patterson (9), reaching as high an incidence as 33% of all gastro enterostomies in some clinics At the New York Hospital, Farr (3) reports 139 cases of perforated peptic ulcer with an operative mortality of 17 9 percent where only the simplest procedures were used This substantiates their views opposing primary gastro enterostomy

Gastric resection as practised by Austrian and German surgeons appears to be too radical a procedure to be consistent with a low primary operative mortality In America, very few proponents have appeared for such extreme measures

FIFTY CASES OF ACUTE PERFORATED ULCERS

Tabulated Statement

Cases					50
Average Age	31	Youngest	19	Oldest	72

THE USE OF THE ELECTROSURGICAL SCALPEL IN RENAL SURGERY*

By W. W. SCOTT, M.D., F.A.C.S., Rochester, N. Y.

From the Department of Surgery, the University of Rochester School of Medicine and Dentistry.

IT is not necessary to dwell in detail on the importance of conservation of renal parenchyma in operative procedures upon the kidney. The complete eradication, by surgical methods, of one particular type of renal pathology does not always guarantee against the recurrence of the same process, or the development of another of equal seriousness. Braasch and Foulds[1], Chute[2], Barney[3] and others have shown that renal calculi tend to recur, following their removal, in at least 15 to 20 per cent. of the cases. In the writer's experience, nothing so impressively drives home the doctrine of conservatism in renal surgery as the appearance of a patient suffering from chronic uraemia due to the presence of calculi in the sole remaining kidney. In such cases the patient's life often hangs in such a delicate balance that any slight mistake in operative judgment, technique or preoperative and postoperative care throws the scales in the wrong direction, with death as the inevitable result. Therefore, in such cases, any procedures that tend to increase the chances of success, no matter how slightly, are worthy of the most careful consideration upon the part of all who attempt renal surgery.

Among the more recent contributions of this nature, Deming's[4] study of the effects upon the renal circulation following various forms of elongation of pyelotomy wounds is most instructive. In this work he demonstrates that the elongation of the pyelotomy incision into the posterior surface of the kidney to the lower pole, does not impair the renal circulation providing the retropelvic vessels are not injured. The same writer, in an experimental study of the effect of various types of sutures upon the renal circulation[5] has shown that mattress sutures, passed from the cortex to the pelvis, control hemorrhage quite satisfactorily and impair renal circulation less than any of the various types of deep transfixing sutures. In one of the cases of this series (Fig. 14) we used this suture and found it to be quite satisfactory.

While considering the problems of renal surgery, it occurred to the writer that the electrosurgical scalpel possessed certain qualifications that recommended its use in this work. In 1911 Moore and Corbett[6] clearly demonstrated that the suturing necessary for control of hemorrhage decreased the kidney function more than the actual sectioning of the kidney. Therefore, if by the use of this instrument bleeding could be materially decreased, not only would better and quicker operative work be possible but fewer sutures would be necessary for hemostasis and consequently there would be less loss of renal function. Furthermore, if bleeding were sufficiently controlled by sectioning the kidney with the electrosurgical scalpel, any dangerous complications that might arise from compressing or clamping the vascular pedicle would be completely eliminated. Also it is reasonable to believe that from the standpoint of control of hemorrhage and sepsis, the use of this instrument offers a very satisfactory method of opening multiple cortical abscesses in cases in which nephrectomy is contra-indicated. It is, also, conceivable that in Rovsing's treatment of polycystic kidneys by puncturing the cysts, the electrosurgical scalpel would be of considerable value.

The writer was considerably encouraged in his belief in the value of the electrosurgical scalpel in certain forms of renal surgery by the experimental work of Pearse and Ward[7]. These investigators, working on dogs, were able to remove a large elliptical segment of the kidney extending from the cortex to the pelvis, by means of the endotherm knife, with only a moderate loss of blood. Bleeding from the larger arteries in the renal parenchyma was completely controlled by clamping and coagulating. No ties or sutures were used to control hemorrhage. Where large disc-shaped areas were removed from the renal cortex there was very little bleeding and no sutures were necessary. This experimental work, along with the excellent results obtained by this method in other fields, seemed to justify its use in renal surgery.

The ideal current for kidney work is one that cuts readily and at the same time seals the severed renal vessels with the least possible destruction of renal parenchyma due to coagulation. The machine used in this series was a spark-gap generator capable of developing a current possessing combined cutting and coagulating properties. Because these generators have not been properly standardized as yet, it is necessary to determine by means of animal experimentation with each machine, what adjustments are required to obtain a satisfactory current for renal surgery before attempting to use it on patients. In our experience the radio tube type of generator does not seem quite so satisfactory for renal surgery as the spark-gap machine.

In the following cases the electrosurgical

* Read at the annual meeting of the Medical Society of the State of New York, at Rochester, June 4, 1930.

scalpel was found to be of considerable value in the control of bleeding:

Case 1. L. K., S.M.H. No. 24453, aged forty-seven. May 9, 1929.

Complaint. Pain in right kidney region.

Family History. Unimportant.

Past History. The patient had an appendectomy performed in 1913 and a gastroenterostomy two years later. He denied venereal infection.

Marital. One child. Wife had two miscarriages.

Present Illness. Ten years before admission the patient first noticed a dull pain just above the crest of the right ilium. The pain lasted but a few days and did not radiate. The last attack, which started two months previous to the patient's admission to the hospital, differed from the previous ones in that the pain, which had been more or less constant since the onset, was so severe as to incapacitate the patient for work. This pain did not radiate and, so far as the patient knew, there had been no hematuria.

Physical Examination. This was essentially negative except for indirect right inguinal hernia. The blood pressure was 140/90.

Special Examinations.

Urine. An occasional pus cell and a few red blood cells.

Phthalein Test. The total output for two hours was 75 per cent.

Blood, Wassermann. 3 plus.

Spinal Fluid Study. Globulin—negative. Thirty-eight pus cells to the field. Wassermann, 4 plus

Radiogram. Staghorn calculus of right kidney pelvis. Seven small calculi in lower pole of kidney (Fig. 1).

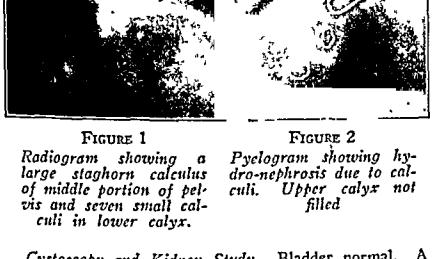

FIGURE 1

Radiogram showing a large staghorn calculus of middle portion of pelvis and seven small calculi in lower calyx.

FIGURE 2

Pyelogram showing hydro-nephrosis due to calculi. Upper calyx not filled

Cystoscopy and Kidney Study. Bladder normal. A number 7 F. catheter was passed to each kidney without meeting obstruction. Urine from each side was uninfected. The differential urea reading was 0.2 gm. per liter on the left side and 1.2 gm. per liter on the right. A stereoscopic right pyelogram was obtained.

Stereoscopic Right Pyelogram. There was a large staghorn calculus filling the pelvis and major calices of the right kidney, preventing filling of the upper minor calyx. The remaining minor calices were enlarged and blunt. In a pocket formed by the enlarged minor calyx, were seven small calculi (Fig. 2).

Operation. Under gas-oxygen anesthesia, by means of the extraperitoneal lumbar approach, the kidney was mobilized and the ureter and pelvis exposed. By extending the pelvic incision into the lower portion of the posterior surface of the kidney parenchyma for a distance of 1 cm with the electrosurgical scalpel, the large staghorn calculus was easily removed. Bleeding was well controlled. It was found that the lower pole of the kidney was quite dilated and it was only possible to locate and remove two of the small calculi without enlarging the incision. Believing that this large pocket in the lower pole offered a favorable site for the formation of more calculi, it was decided to resect this area and remove the remaining small calculi at the same time. A rubber-shod clamp was placed across the vascular pedicle and then, by means of the electrosurgical scalpel, the lower half of the pole of the kidney was resected in the form of a wedge-shaped mass so as to allow better closure of the incision (Fig. 3). The remaining cal-

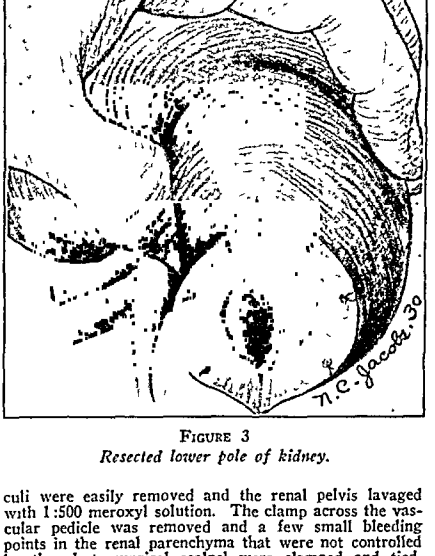

FIGURE 3

Resected lower pole of kidney.

culi were easily removed and the renal pelvis lavaged with 1:500 meroxyl solution. The clamp across the vascular pedicle was removed and a few small bleeding points in the renal parenchyma that were not controlled by the electrosurgical scalpel were clamped and tied. The incision was closed with three mattress sutures of zero chromic catgut placed close to the edges of the wound so as to destroy as little tissue as possible. A thin strip of muscle was placed over the surface of the renal incision and tied in position by means of the long ends of the mattress sutures (Fig. 4). The extended pyelotomy wound was closed with a continuous 00 chromic catgut suture. Bleeding was completely controlled. The kidney was dropped back in place and a rubber tube and cigarette drain were placed for drainage. The muscles and fascia were approximated by a continuous No. 2 chromic catgut suture. The skin was closed with interrupted silk sutures. The patient was in good condition upon leaving the operating table.

Comment. It is our hope that the resection of the dilated lower calyx removed a favorable site for new stone formation and at the same time left a certain amount of kidney reserve that might be of great value if stones developed in the other kidney. While the electrosurgical scalpel did not completely control

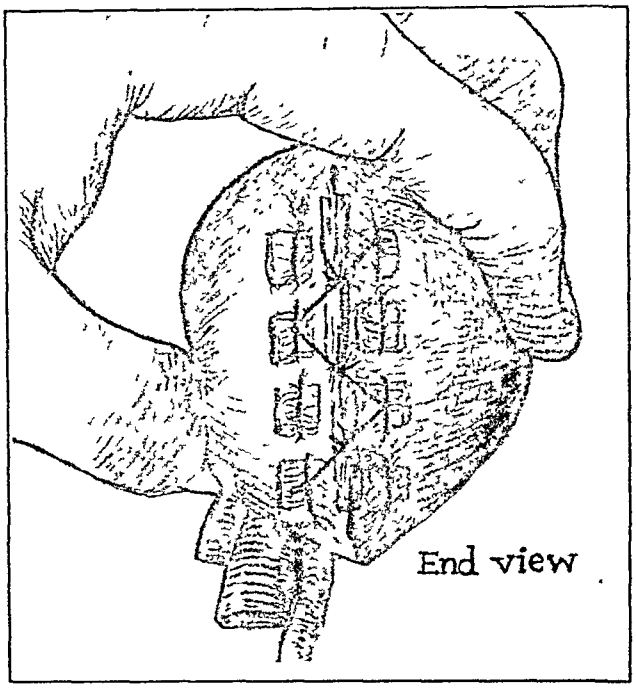

FIGURE 4
Closure of kidney wound.

hemorrhage, it was possible to obtain satisfactory hemostasis with fewer sutures than would have been necessary had it not been used.

Case 2. A K., S.M.H. No. 21141, aged forty-five. October 22, 1929.

Complaint. Pain in the right kidney region and smoky urine

Family History Unimportant.

Past History. In January 1929, the patient was admitted to the hospital and treated for paroxysmal tachycardia. Five months later he received several treatments for chronic antrum sinusitis. His past history was otherwise negative.

Present Illness. Seven weeks before admission, after lifting a heavy object, the patient first noticed pain in the right kidney region which radiated down the course of the right ureter. Two weeks later he noticed smoky urine and burning during urination. These symptoms were present on admission.

Physical Examinatoin. The principal findings on physical examination were myocarditis, emphysema, hemorrhoids and fistula in ano. The blood pressure was 165/105.

Special Examinations.

Urine. Albumin ++, pus +, red blood cells ++.

Blood. R.B.C. 4,620,000. W.B.C. 14,000 and Hb. 95 per cent.

Blood Chemistry. Non-protein nitrogen 31 mg. per 100 c c.

Phthalein Test. Appearance time 4 minutes, output 70 per cent. in 2 hours.

Plain Radiogram. The plain radiogram showed a stone in right renal pelvis (Fig. 5).

Cystoscopy and Kidney Study. The bladder capacity was 500 c.c. The bladder was normal. A number 7 F. ureteral catheter was passed to each kidney pelvis. The urine from the right side contained a few pus cells. No organisms were found on either side. The differential urea reading was 0 3 gm. per liter on the right side and 1 1 gm. on the left. The phthalein appeared on the left side in 3½ minutes and 4 minutes on the right, while the ouptut for one-half hour on the left side was 17 per cent. and on the right 13 per cent. A stereoscopic right pyelogram was obtained.

Stereoscopic Pyelogram. The pyelogram showed a stone in the right kidney pelvis and early hydronephrosis (Fig. 6).

Operation. On November 7, 1929, under gas-oxygen anesthesia, the kidney was approached through the extraperitoneal lumbar route. On exposing the upper pole of the kidney, marked adhesions between the true capsule and the perirenal fat were found. These bands of adhesions were clamped, cut and tied. In doing this a tear about 2 cm. in length, was made in the cortex of the upper pole of kidney, directly over the upper calyx. Bleeding was controlled by a pack and the lower pole of kidney freed. The ureter was then isolated and traced to the kidney pelvis. The stone was located in the upper calyx of the kidney. In view of the fact that a tear already existed in the kidney substance at this point, the writer suggested that the incision be carried down to the stone by means of the electrosurgical scalpel. The stone was easily removed and bleeding was practically controlled by this instrument. The edges of the incision were approximated by two mattress sutures of No 1 chromic catgut placed close to the edge of the wound. Pieces of muscle were placed between the kidney capsule and the suture to prevent the sutures from cutting into the kidney substance. Bleeding was completely controlled. The kidney was dropped back in place and a small rubber tube was placed for drainage. The fascia and muscle surfaces were approximated by a continuous

FIGURE 5
Stone in right kidney pelvis.

FIGURE 6
Early hydronephrosis. Stone in region of ureteropelvic junction.

No. 2 chromic catgut suture, reinforced by three silver wire stay sutures. The skin surfaces were approximated by interrupted black silk sutures. The patient left the table in splendid condition.

Postoperative Treatment. The patient's convalescence was very satisfactory. On December 7, 1929, the patient was operated for fissure in ano and hemorrhoids He left the hospital four weeks later. He has been followed for several months in the out patient clinic and is in excellent condition.

Comment. In this case electrosurgical scalpel practically controlled hemorrhage.

Case 3. T.J., S.M.H. No. 10250, aged forty-one years, October 6, 1929.

Complaint. Frequency, dysuria and pain in right kidney region

Past History Aside from a history of five distinct Neisser infections, the past history was essentially negative.

Present Illness. Since early childhood the patient had been bothered by frequency, urgency, dysuria and pyuria When 35 years of age he passed a calculus from left kidney and, upon x-ray examination, another stone was found in the kidney. A left nephrectomy was performed at that time. Five years later (May, 1926) he was operated upon for appendicitis One month later he became very ill, having chills, fever, nausea, vomiting, pain in right kidney region and complete suppression of urine for a period of four days. Five weeks later he had a similar attack of five days' duration. In March, 1927, he passed three calculi On October 10, 1927 he was admitted to the Strong Memorial Hospital where a diagnosis of right nephrolithiasis was made and a course of oral medication instituted. In December 1928 he was admitted to the hospital complaining of pain in the right lower quadrant and anuria of 20 hours' duration A catheter was passed to the right kidney pelvis and drainage established Three days later a pyelogram was obtained and it was determined that the patient had a calculus in the lower calyx. In view of the fact that the calculus seemed to be in a fixed position in the lower calyx and because the patient was apparently quite well within a few days from the time drainage was established, he was discharged from the hospital with instructions to return each month for observation He was not seen until *ten months* later when he again entered the hospital in complete anuria of about 24 hours' duration

Physical Examination. Temperature 38° C Respirations 20 Pulse 108. Blood pressure 122/68. The patient was a little drowsy and his tongue was coated There was marked tenderness over the right upper quadrant and in the costo-vertebral region The lower pole of the right kidney could be palpated and was found to move slightly with respiratory movements

Special Examinations

Blood Chemistry. The N P N. was 100 mg per 100 c c

FIGURE 8

Hydronephrosis due to calculi in a sole remaining kidney.

FIGURE 7

Calculus in lower and middle calices of kidney

Urine. The patient was in anuria on admission. A ureteral catheter was passed at once to the right kidney and 65 c.c of thick, pussy urine was obtained from which, on culture, grew Bacillus Coli and Bacillus Morgani

Phthalein Test. Three days after admission the Phthalein output for two hours was 25 per cent

Blood Examinations W B C. 7,820 R.B C. 4,000,000. Hg. 72 per cent.

Radiogram The plain abdominal picture showed a calculus in the lower calyx and a new large, faint shadow in the middle portion of the renal pelvis, probably caused by a calculus (Fig. 7).

Stereoscopic Pyelogram There was marked hydronephrosis. In the lower pole of kidney there was a large calculus The middle portion of the pelvis was filled with a large, relatively faint shadow probably representing multiple small calculi. The pelvis was of the intrarenal type (Fig 8)

Preoperative Treatment. Inasmuch as the patient was in anuria, on admission, and his N.P.N. was 100 mg. per 100 c c, a No 9 F. catheter was passed to the kidney

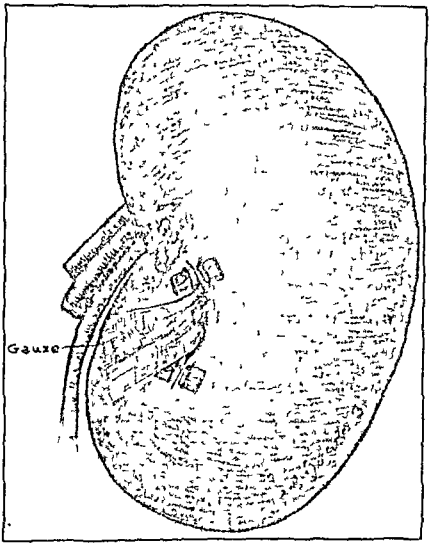

FIGURE 9

Ends of incision approximated by mattress sutures. Gauze pack used to keep rest of incision open.

at once and 65 c c of thick, pussy urine was obtained The kidney pelvis was lavaged with warm, sterile boric solution and the catheter left in place, to maintain drainage. With the exception of a few occasions when the ureteral catheter was removed in order to rest the ureter, the kidney was drained for a period of 20 days At the end of this time it was quite evident that the patient had reached *his maximum condition His N.P.N,* was 60 mg. per 100 c c. and his phthalein output was 30 per cent for two hours During this period fluids were forced by mouth and, in addition, he was given numerous intravenous injections of 5 per cent glucose solution.

Operation, On October 15, 1929 an extraperitoneal lumbar nephrolithotomy was performed, under gas-oxygen anesthesia As the kidney was approached it was found that the fatty capsule was edematous and indurated, the result of a direct extension of an inflammatory process of the kidney. The fatty capsule having been separated from the kidney, the ureter was then located It was found to be considerably enlarged and bound down by scar tissue formation When the ureter was followed to the kidney it was observed that the patient had an intrarenal pelvis and that a nephrolithotomy would be necessary. The kidney was greatly enlarged, irregular, and it was at once evident that the lower half of the renal pelvis was markedly dilated By means of

the electrosurgical scalpel an incision 3.5 cm. in length and penetrating through the pelvis was made in the lower posterior surface of the kidney, in a direction followed by a line extending from the junction of the ureter with the intrarenal pelvis to the extremity of the lower calyx. The course of the incision followed, as accurately as conditions permitted, the direction advocated by Deming. Cultures of the urine from the kidney pelvis showed a massive growth of Staphylococcus aureus and Bacillus proteus. There was but very little bleeding. The large calculus in the lower calyx was first removed. It was then found that the middle portion of the renal pelvis was filled with a large number of small calculi varying from 2 mm. to 1cm. in diameter. By means of a gall-bladder spoon and a thorough lavage with sterile salt solution, all remaining calculi were apparently removed. Because of the history of reflex anuria following the removal of his other kidney, the operator decided tc put a gauze pack in the pelvis rather than a tube. The extremities of the incision were approximated by means of two mattress sutures with No. 0 catgut. These were placed close to the edges of the incision and pieces of muscle were inserted between the sutures and the capsule of kidney to prevent as much as possible interference with the blood supply (Fig. 9). The kidney was returned to its normal position and a rubber drainage tube placed down to the renal incision. The fascia and muscles were approximated by means of a continuous No. 2 chromic catgut suture, reinforced by three silver wire stay sutures. The skin was closed by interrupted silk sutures. The patient left the table in fair condition.

Postoperative Treatment. Although a fluid intake of about 5000 c.c. a day was maintained, his N.P.N. gradually increased for several days after operation until it was 113 mg. per 100 c.c. on the eleventh day (Fig. 10).

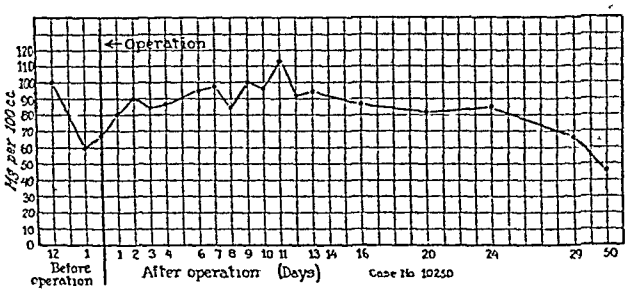

FIGURE 10

Chart of the non-protein nitrogen concentration in blood before and after operation.

He received 500 c.c. of 10 per cent. glucose twice daily from the second to the twelfth postoperative day. After the first five days it was necessary to give 10 units of insulin with each injection of intravenous glucose because of the rise in blood sugar. His wound became badly infected and he developed a marked secondary anaemia. Following a transfusion of 500 c.c. of blood on the ninth day, there was a marked improvement in the condition of the wound. Seven weeks after operation his N.P.N. was 48 mg. per 100 c.c. and his phthalein output 30 per cent. for 2 hours. The patient left the hospital in excellent condition. He has been followed at intervals since his discharge and as yet there has been no new stone formation.

Comment. Bleeding was so well controlled that it was unnecessary to clamp or compress the vascular pedicle and, therefore, the fear of injuring the renal vessels was not experienced. Of course, in the hydronephrotic kidney the blood supply is not as bountiful as in the normal one. The postoperative care is very important in these cases.

Case 4. S.R., S.M.H. No. 12901, aged twenty-two, January 18, 1930.

Family History. Not important.

Past History. Unessential.

Present Illness. On November 1, 1929, following a long walk, the patient first noticed blood in his urine. He consulted his family physician who made a diagnosis of diabetes mellitus and gave him some pills. Not long afterwards he noticed a dull pain in the right kidney region following all forms of strenuous exercise. The pain did not radiate and disappeared with rest in bed. Following the attack of gross hematuria that initiated the onset of the patient's symptoms there was no further bleeding. During the year preceding his admission to the hospital there had been a gradual increase in urinary frequency and a loss of twenty pounds in weight.

Physical Examination. The physical examination was essentially negative. Blood pressure 106/68.

Special Examinations.

Urine. Sugar, trace. Acetone +. Otherwise negative.

Phthalein Test. Appearance time 2½ minutes, output 55 per cent. for the first hour.

Blood Chemistry. Blood sugar 65.4 mg. per 100 c.c. N.P.N. normal.

Radiogram. There was a stone too large to pass in the lower pole of the right kidney.

FIGURE 11

Pyelogram showing stone in kidney pelvis.

Cystoscopic Examination. The bladder was normal. Number 7 F. catheters were passed to both kidneys without meeting any obstruction. The urine from each side was free from infection and the urea concentration was the same on each side. On differential phthalein test, the drug appeared on each side in 2½ minutes and the output for one-half hour was 30 per cent. from each kidney. A stereoscopic pyelogram of the right kidney was made before the catheters were withdrawn.

Stereoscopic Pyelogram. There was a stone too large to pass in the lower minor calyx of a kidney having an intrarenal pelvis (Fig. 11).

Treatment. The diabetic condition was regulated and then a right nephrolithotomy performed.

Operation. Under gas-oxygen anesthesia, the kidney

and upper third of the ureter were exposed by means of the extraperitoneal lumbar approach. It was at once determined that because of the extreme degree of intrarenal pelvis a nephrolithotomy was indicated The stone was palpated in the lower pole of the kidney and then, by means of the electrosurgical scalpel an incision 2 cm. in length was made on the posterior surface of the kidney directly over the lower minor calyx and the stone removed. It was unnecessary to compress or clamp the vascular pedicle to control the bleeding, which occurred from only one point in the incision and was only slight. The edges of the incision were approximated by means of one mattress suture, placed close to the edges of the wound. Pieces of muscle were placed between the kidney surface and the suture as a means of protection against cutting. The kidney was dropped back in position and a rubber tube placed down to the incision for drainage. The fascia and muscles were approximated by a continuous No. 2 chromic catgut suture, reinforced b three silver wire stay sutures. The skin surfaces were approximated by interrupted black silk sutures. The patient left the table in good condition.

Postoperative Course. His convalescence was satisfactory, the patient leaving the hospital three weeks after his operation. He has been followed in the outpatient department because of the diabetes mellitus. He has had no recurrence of kidney trouble.

Comment. Although the patient had diabetes, the convalescence was free from any complications.

Case 5. R.L., S.M.H. No. 29797, aged forty. November 18, 1929.

Complaint. Recurrent attacks of pain in left kidney region

Family History. Not important.

Past History. Unessential.

Present Illness. In December, 1921, the patient had his right kidney removed because of calculi. Two years later he began to notice pain in the left kidney region. This pain recurred from time to time until June 1929 when he developed anuria. A radiogram showed a stone in the lower portion of the left ureter. A ureteral catheter was passed but the anuria persisted until the ureteral catheter was removed six days later. He was sent to the Mayo Clinic and on his way there had another attack of anuria. Just before his arrival at that Clinic he passed the stone into the bladder. The calculus was removed from the bladder by means of a cystoscopic rongeur and an operation for nephrolithiasis advised but refused by the patient. Following his return home he was practically incapacitated by pain in the kidney region. He was first seen by the writer in November 1929 when an operation was advised. In December 1929 the patient passed another calculus and in January 1930 he entered the hospital for study and operation.

Physical Examination. Temperature 37°C. Pulse 80 Blood pressure 120/80. The left kidney was palpable, considerably enlarged but not tender. There was a small hydrocele on the left side of scrotum.

Special Examinations.

Urine. Albumin ++, pus +++, R.B.C. + Bacilli and cocci.

Blood Chemistry. The N.P.N. was 60 mg. per 100 c.c. and the creatinin 3.0 mg. per 100 c.c.

Phthalein Test. The total phthalein output for 2 hours was 28 per cent.

Cystoscopic Examination. Bladder capacity 300 c.c. The bladder mucosa was inflamed and congested. A No. 7 F. ureteral catheter passed easily to the left kidney pelvis. The urine from this side was loaded with pus cells and Bacillus coli. A stereoscopic pyelogram was obtained.

X-ray Examinations.—"Radiogram." The radiogram showed a large staghorn calculus filling the right kidney pelvis and a number of smaller stones in the lower pole of the kidney (Fig. 12).

Stereoscopic Pyelogram. There was extensive hydronephrosis with bulbous enlargement of the minor calices. A staghorn calculus filled the middle portion of the renal pelvis and in the dilated lower calyx were a number of smaller calculi (Fig. 13).

Operation. Under gas-oxygen, ether anesthesia, the kidney was approached through the usual extraperitoneal lumbar route. The kidney was found to be practically cemented in place with scar tissue. The ureter was greatly enlarged and embedded in inflammatory tissue to such an extent that the kidney pelves and upper portion

FIGURE 13

Advanced pyonephrosis due to calculi in a sole remaining kidney.

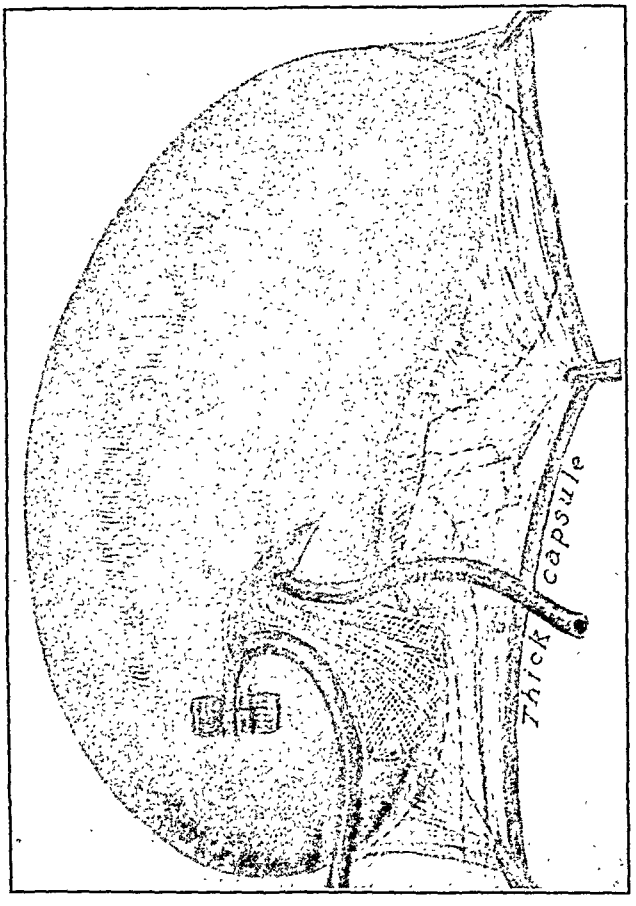

FIGURE 12

A larg ecalculus in middle calyx and many small calculi in dilated lower calyx.

of the ureter could not be clearly indentified At this stage the patient went into profound shock, having a blood pressure of 50/40 and a pulse rate of 120 per minute. He was given cardiac stimulants and 500 c.c. of intravenous glucose. An incision was made through the fatty and true capsules and the kidney exposed by means of an intracapsular maneuver. It was found to be markedly enlarged and of the pyonephrotic type. On its surface were numerous small abscesses, some of them as large as a ten-cent piece in diameter. The patient's condition was so bad at this stage that no attempt was made to free the ureter and pelvis from the surrounding scar tissue. By means of the electrosurgical scalpel an incision 4 cm. in length and extending into the dilated renal pelvis was made on the posterior portion of the lower pole of the kidney. The direction of this incision followed the course of a line extending from a pyelotomy incision down the posterior surface of the kidney to the central extremity of the lower calyx. Bleeding was so well controlled that it was unnecessary to make pressure upon the vessels of the renal pedicle. A large staghorn calculus and many small calculi were removed from the pelvis. The urine in the pelvis was thick and heavily infected. A Dakin's tube was placed in the upper and lower poles of the kidney and held in place by gauze packs. A bleeding vessel in the lower end of the wound was controlled by a mattress suture of 00 chromic catgut placed in the manner described by Deming. The lower end of the wound was approximated by placing a similar suture opposite the first and tying the two together (Fig. 14). Bleeding was completely controlled. A cigarette drain and a rubber tube were placed down to the renal incision for drainage. The muscles were approximated by a continuous No. 2 chromic suture, reinforced by three silver wire stay sutures. The skin was approximated by black silk sutures. The patient's condi-

tion was extremely serious throughout the operation and the operator was compelled to work as rapidly as possible.

Postoperative Course. On the day of operation the patient received 1400 c.c. of intravenous glucose, 5 per cent. solution, and 2000 c.c. of normal salt solution by hypodermoclysis. For ten days a fluid intake of 5000

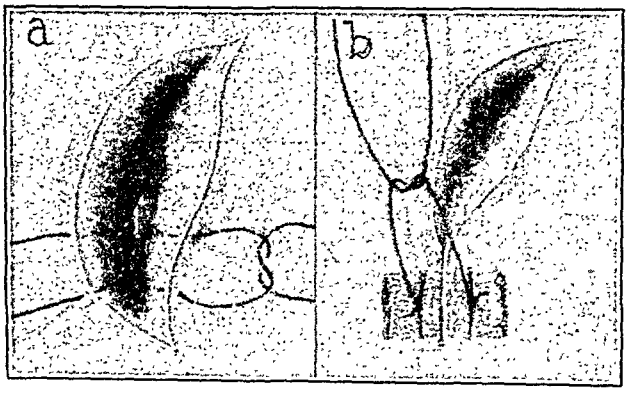

FIGURE 14

Kidney following removal of calculi showing Dakin's tubes placed for drainage and irrigation. a and b Deming suture in lower end of incision.

c.c. daily was maintained. During the first five days the patient received at least 500 c.c. of 10 per cent. glucose each day. In spite of the high fluid intake there was a gradual rise in the N.P.N. for the first two days after operation (Fig. 15). During the first two days the kidney pelvis was irrigated, twice daily, with warm sterile boric solution, by means of Dakin's tubes. Thereafter, until the tubes were removed on the ninth day, 1 per cent. mercurochrome solution was used. On the seventeenth day after operation, the N.P.N. started to drop and seven days later it was 48 mg. per 100 c.c. The patient was apparently in excellent health when he left the hospital. He has resumed his work and when last seen, on May 24, 1930, a radiogram was negative for calculi. His urine was still infected with bacilli but the cocci were no longer present.

Comment. There was but one bleeding point that was not completely controlled by the electrosurgical scalpel. This was easily stopped with the type of mattress suture described by Deming. The combined use of the electrosurgical scalpel and the Deming suture offer a very satisfactory method of controlling bleeding and approximating the edges of the nephrotomy wounds.

Discussion

The result obtained in the use of the electrosurgical scalpel in the above cases would seem to warrant its use in certain type of renal surgery. In only one of these five cases was it necessary to clamp the vascular pedicle and in this instance the lower pole of the kidney was resected. In this case

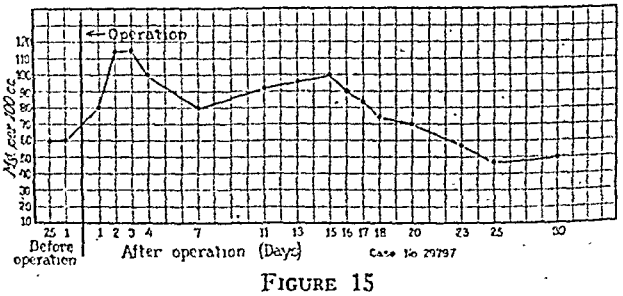

FIGURE 15

Chart showing the non-protein nitrogen concentration in blood before and after operation.

there was less bleeding and fewer sutures were required for its control than would have been necessary had this method not been used. The knowledge that the possibility of renal injury resulting from compressing or clamping the vascular pedicle to control bleeding had been completely eliminated was a matter of no little comfort to the operator, especially when operating upon the patients having calculi in a sole remaining kidney of low functional value. Furthermore, in these cases the bleeding was very moderate, requiring but very little suturing to control and consequently the patient's chances for recovery were increased in proportion to the amount of functional renal parenchyma conserved. Of course, success, in cases of this type depends upon the preparation of the patient for operation and the postoperative care, as well as the conversation of functional renal parenchyma at the time of operation. A mattress suture placed in the manner described by Deming was used in one

of these cases and found to be very satisfactory. It would seem that the use of the electrosurgical scalpel and the Deming suture offer a combination of great value in operative procedures upon the renal parenchyma

Conclusions

The use of the electrical scalpel in operative procedures upon the renal parenchyma greatly decreases the amount of hemorrhage

Because bleeding is better controlled by this method, fewer sutures are necessary and consequently there is less loss of renal function.

The decreases in the amount of bleeding permits quicker and better operative work.

RECURRENT FIBROCYSTIC OVARIES TREATED BY X-RAY

By J. CRAIG POTTER, M.D., ROCHESTER, N. Y.

FIBROCYSTIC ovarian disease is often treated by palliative measures, such as resection or by puncturing the cysts, when, from a health standpoint, better end results would be obtained from ovariectomy. Pregnancy, however, results often enough to justify these procedures. In the final outcome, recurrences or tender, adherent ovaries are apt to occur. In these recurrent cases, which have had one or more abdominal operations, one hesitates to operate for a return of symptoms, as the ovary must be removed and more adhesions may result. I have treated four such patients by means of *x*-ray with good results. Being unable to find in the literature any cases so treated, I am reporting them.

The first patient, thirty-two years old, had had an appendectomy in 1916. In 1926 the left ovary was resected and cysts in the right ovary were punctured. In 1928 a perineal repair was done. She complained of irregular, painful periods Examination showed a recurrent left cystic ovary, the size of an egg and an adherent, small right ovary. An *x*-ray menopause relieved the symptoms, and the cyst disappeared. Two years later the periods returned with pain, but the cyst did not return. Further *x*-ray to stop the periods has cleared up the pelvic discomfort

The second patient at twenty-seven had an egg-sized, microcystic ovary removed for pain on the right side and frequent, profuse, painful periods There was also a small subserous myomata uteri. A year later the remaining ovary became egg-sized and the periods frequent, prolonged and profuse. A twenty per cent *x*-ray dose to the ovary has reduced the ovary and periods to normal.

The third case had bilaterally resected cystic ovaries. Following operation she had intermenstrual pain each month on the left. The ovary was on that side in a small, tender adherent mass A menopause dose to the left side has stopped the pain, softened the mass, the fornix is no longer tender, and menstruation is regular and normal

The fourth case had an orange-sized, follicular, cystic left ovary removed four years previously and a resection of the right ovary. At forty-two the periods became more profuse and the right ovary the size of a tangerine. A menopause dose of *x*-ray stopped the flowing, and the ovary has become small and strophic. The blood-count is normal for the first time in five years

I am aware that ovarian cysts should be removed, because of the danger of malignancy, the ease of operation, and good end results It is the handling of benign, recurrent, fibro-cystic ovaries, where they have been conservatively operated and have later caused discomfort, that I am emphasizing; also the interesting observation that the pain not only disappeared in these radiated cases but also the cystic enlargement. It would seem unlikely that a pain not associated with ovulation or menstruation would be improved, unless the disappearance of the cysts would decrease the painful pressure and traction The results obtained in these cases suggest that in certain patients the *x*-ray is a valuable means of treating the condition.

THE PLACE OF SPAS IN THE TREATMENT OF CHRONIC DISEASE*

By L. W. GORHAM, M.D., ALBANY, N. Y.

FROM early Græco-Roman times natural mineral water and baths have been utilized in the treatment of disease. Even the Father of Medicine himself, Hippocrates, may be regared as having had some idea of the spa method of treatment. The site of the temple at Cos where he practiced was chosen especially for its natural beauty and pleasant climate. In addition, considerable use was made of hydro-therapeutic and physical methods of treatment, although the psychic effect derived from a mystic ritualism was probably an important feature. At one time there were well over fifty of these temples of health in Greece, many of them situated near some spring whose water was supposed to have a special healing property.

For centuries the custom of seeking relief from chronic ailments by visiting the spas has been generally accepted in Europe, not only by the laity who throng there by the thousands, but by large numbers of well qualified physicians, who have consistently referred patients to these resorts for treatment. It is estimated that at least one million visit the spas of Europe annually.

In our own country, by contrast, this form of therapy has been accorded but slight recognition by the public, and among physicians as a rule there is marked scepticism as to its value. The reasons for this are apparent. Extravagant and unproven claims as to the specific action of mineral waters which are commonly made, plus ignorance as to what really constitutes the spa regime as practiced by modernly trained physicians at some of the old well established spas, have caused the profession in the United States generally to condemn the entire idea or to dismiss all the favorable results as being due entirely to psychic effect.

The claims made by the majority of the spas are fanciful. The type of advertising usually emanating from lay sources would often of itself tend to discredit the spa whose efficacy it is intended to support. The statement that certain waters are curative in a long list of chronic conditions reminds one of the cure-all claims made for the most palpably fraudulent patent medicines.

When one comes to examine in detail the literature from the various spas of Europe especially the lists of diseases for which the particular springs are indicated, one is struck by their great similarity. A small number limit their claims to a few diseases, but this is the exception. One must necesssarily conclude therefore that either the claims made for specific effect of mineral waters are unfounded, or else that the beneficial results apparently obtained are due to a combination of factors in the spa regime—certain broad principles of therapeutics which are common to all spas.

There are two points of view among spa physicians regarding the action of mineral waters. There are those who have an unbounded faith in the potency and specific curative effects of the mineral waters and baths of the particular spa in which they are interested —an action as specific as quinine is for malaria. They believe that the waters contain certain intangible properties which modern science can not measure, and they brush aside all chemical and pharmacologic investigation which has failed to demonstrate specific curative effect of mineral water. When asked to furnish evidence to support their view, such men can only point to clinical results, claiming that the method has lasted for centuries, and is increasing rather than decreasing in popularity. There is however also a group of spa physicians, smaller perhaps numerically, who take a much more rational and more readily understandable point of view. To them the admittedly good results which are often obtained may be explained more simply. They regard the mineral waters as compound drugs whose action on the human organism is susceptible to physiologic and pharmacologic study. They point out that the spa treatment rarely if ever consists solely of drinking or bathing in spring water, but that many other factors, such as rest, diet, exercise, diversion, and climate, play a definite part. They conclude that the application of certain general broad principles of treatment followed more or less at all spas account for the good results obtained. Such men do not believe that mineral waters are inert however, and devoid of physiologic action. Large clinical experience has revealed the fact that certain springs have an aperient effect acting mainly upon the intestine and increasing elimination through this means, and others act principally upon the kidneys producing a diuretic action. There is scientific evidence to show that mineral waters containing iodine may have an effect upon the thyroid. When employed externally, baths containing a high percentage of carbonic dioxide gas have been shown to have a definite objective effect upon the peripheral circulation.

It is quite natural that physicians generally should be more interested in acute forms of

* Read before the N. Y. Academy of Medicine at a meeting held on Jan. 5th, 1931, under the auspices of the Committee on Public Health Relations.

disease, especially where a specific remedial agent is at their command, and in which a clear cut therapeutic success may be obtained. It is equally true however that the problem of chronic disease and its alleviation or cure is a pressing one. The failure of physicians to utilize all legitimate methods of treatment, including physio- and psycho-therapy, has undoubtedly led to the development of many cults. There has been some change since the World War however and the passage of the Workmen's Compensation Act. Our leading hospitals are now generally provided with special departments where various forms of mechano-, electro-, and hydro-therapy are employed. So too there are signs of an awakened interest on the part of the public as to the value of the spa treatment.

The Legislature of the State of New York in 1929 created by official act a commission to make a comprehensive study and survey of the mineral springs at Saratoga with a view to their development along the lines of the best European spas. In the first place the commission sought expert technical advice as to the quality and quantity of the water supply. It also cooperated with the New York Academy of Medicine inviting a committee of five medical men, to visit a number of European spas and to answer the question as to whether or not in their opinion, it was justifiable to recommend the further development of the spa method of treatment at Saratoga.

At the outset the group was rather sceptical to the value of the spas and quite ignorant of the methods employed in them. After a visit, either jointly or separately, to the principal spas of Austria, Czecho-Slovakia, England, France, Germany and Hungary, a total of nineteen in all, the committee unanimously agreed that "The Spas of Europe provide desirable and effective means for the treatment and relief of many chronic ailments."

The information which led us to such a conclusion came from the recognition of the important fact that the spa treatment as practiced by well trained reputable physicians at the best European spas comprises, in most instances, all that is generally deemed advisable and ethical in the treatment of chronic disease in this country.

It is important to define what is generally meant by a spa and by the spa treatment. A spa is a health resort having a natural mineral spring or springs of a distinctive type. The spa treatment on the other hand denotes the therapeutic use of many agents both phychical and psychical.

The physical agents may be enumerated as follows:

Physical Factors:

1. Natural mineral waters for drinking and bathing.
2. Special baths and douches of various types, message douche, needle douche, etc.
3. Other physical methods, such as massage, exercise, mechano-therapy, inhalations, and electro-therapy.
4. Climate, diet, general regime.

Psychical Factors:

1. Change of scene and environment.
2. Removal of business, family, and other worries.
3. Recreation and diversion of various sorts.

It is not merely the taking of a special water or the use of a distinctive type of mineral bath which constitutes the modern treatment at the spas, but rather the application of a combination of rational procedures which are believed to be beneficial in chronic disease.

The regimen is built up about the drinking of, and bathing in, mineral waters; but it includes the strictest and most explicit directions as to rest, diet, exercise and various forms of physio-therapy. The change of scene, the elimination of disturbing home environmental factors, the enjoyment of the beauties of nature, good music and other diversions, all combine to produce a favorable effect upon the body and mind of the patient. Drugs are used when indicated, but constitute a minor part of the general therapy.

Organized and applied in this manner the best spas make available to practicing physicians a variety of places for patients suffering from chronic disease for treatment under medical supervision. In the majority of instances patients come with letters from their home physicians containing clinical and laboratory data bearing on their condition.

The physicians practicing at the spas vary in type and ability as much as they do in any large city. A few outstanding men have had previous connections with large medical clinics and have had excellent clinical and laboratory training. Still others make it a practice to spend part or all of the winter months working in some medical center.

During the pressure of work of the busy spa season it is hardly to be expected that practicing physicians would have time to keep exhaustive clinical records, or do any fundamental investigation. In many of the leading medical schools, however, balneology is taught either as a part of therapeutics or pharmacology, or as a special elective subject. A visit by the students to one of the spas with special lectures on the methods employed is given as

part of the course in some of the universities. In almost every country there exists a national balneological society and the International Balneological Association has a meeting every year. Many European countries have established Institutes of Balneology and Hydrology at certain spas where studies of the physical and chemical properties of the mineral waters are made. In association with these institutes clinical-pathological and *x*-ray laboratories are maintained for the use of the practicing physicians. Physio-therapy is made available in every form and under the direction of specially trained physicians and attendants.

Although no scientific proof exists which indicates a specific direct curative effect of mineral water upon any pathologic condition, the fact remains that thousands of people visit the different European spas annually and in increasing numbers. Clinicians of high standing outside of the spas, while not claiming specificity for the waters, do not hesitate to attest the beneficial effects of spa treatment often surpassing the results obtained in chronic disease at home.

The Advisory Medical Committee which made the survey of the European spas in 1929 for the Saratoga Springs Commission filed its report and made the following recommendations which were presented to the Legislature of the State of New York:—

1. "The committee believes that something of the type of the conservative spas of Europe should be developed in connection with Saratoga Springs, in view of the existence there of springs whose chemical composition is considered suitable for the treatment of certain conditions. The committee is of the opinion that development should proceed in a very conservative way. No attempt should be made to advertise Saratoga in the highly objectionable and misleading manner which is being almost universally employed by the spas of Europe.

2. "It is known that the saline alkaline waters of Saratoga Springs have a diuretic and aperient effect; and there is justification for the belief that the naturally carbonated waters of Saratoga have a physiological effect on the circulation, and that this effect is beneficial in selected cases of circulatory disease. In the judgment of the committee, the situation and climate of Saratoga are ideal for the care of certain forms of heart disease from May to November.

"No attempt should be made to regard Saratoga as a 'cure-all.' Its development should be limited to the treatment of persons chronically ill. This need is particularly felt for patients with diseases of circulation, for the prevention of heart failure and the building up of cardiac reserve, for patients with neurasthenia and the psychasthenias, and with certain chronic metabolic diseases.

3. "The development of Saratoga should proceed along the lines of well-considered policies, administrative and medical. The carrying out of the plan should be gradual, certain features of it being developed ahead of others.

4. "The two immediate needs are: (a) the formulation of a wise medical policy; and, (b) the development of the environment.

5. "With reference to medical policy, the committee recommends:

(a) That a conference be arranged with the officers and trustees of the Medical Society of the State of New York to secure their advice concerning projected developments;

(b) That conferences be held with those among the local practitioners at Saratoga who have shown interest in the development of Saratoga, and in the science and art of balneology, and

(c) That steps be taken toward the establishment of a scientific institute at Saratoga whose functions should be threefold.

The first function would be to provide modern laboratory facilities for diagnostic work, this is to include facilities for radiology, cardiology, basal metabolism, serology, bacteriology, and other diagnostic aids.

The second department, closely linked to the laboratory, would be devoted exclusively to research work in balneotherapy, and other methods of treatment of chronic disease. This department would offer the physicians of the State educational opportunities for the study of the nature and treatment of chronic diseases.

The third department would be given over to the study of the geology of the district and the physical and chemical properties of the waters, this department to be under the direction of a competent modern chemist; while the laboratory and research divisions are to be under the direction of a skilled medical director with a good clinical background, and of a research type of mind. The research and experimental work, as well as the educational facilities, might be associated with one or more medical schools of the State.

The relationship of the institute to the medical practitioners should be worked out in conference with representatives of the State Medical Society and of the local physicians.

(d) In connection with this institute, a fully equipped department of physiotherapy should be developed. It should comprise facilities for the various kinds of physiothermo-, hydro- and electro-therapy, as well as inhala-

toria, gas baths, sun baths, open air as well as enclosed gymnasia, and other features of special therapy.

(e) The institute should be built on State property in close proximity to the bathing establishments. In its directly utilitarian aspects, i. e., in its laboratory work and its physio-therapeutic equipment, it should be built and maintained by the State, although in all probability the charges made for service rendered will cover the cost of its maintenance. For the research work, which would be one of its outstanding features, continuous maintenance should be assured. This institute should be managed by a board of trustees, or a board of scientific control, appointed in a manner which will properly safeguard its purpose.

(f) The selection of the Medical Director and his staff should be the responsibility of the board of trustees or the board of scientific control.

(g) It would, perhaps, be desirable to consider a plan whereby felowships would be granted to young physicians to travel and study abroad, and to organize, at Saratoga or elsewhere, courses in balneotherapy when the opportune time comes.

(h) The clinical material for research purpose could come from both the ordinary patients and the patients who would be accommodated free of charge, or at greatly reduced cost. A rule should be adopted that no one could pursue a course of treatment at Saratoga without medical direction by physicians recognized by the management of the spa."

The commission also stressed the importance of making the environment as attractive as possible, realizing that much of the charm of European spas is due to the care with which opportunities for recreation and diversion out-of-doors have been provided.

In conclusion, I think we may safely say that there is a definite place for the development of the conservative type of spa treatment in the United States. It must necessarily be a slow growth, and should be carried out as already suggested, along broad educational lines, with provision for critical study and proper evaluation of results.

MORTALITY FACTORS IN THYROID DISEASE

By F. H. LAHEY, M.D., F.A.C.S., BOSTON, MASS.

Thyroid disease possesses a quite definite mortality rate either treated or untreated, under operative or non-operative measures. Because of the fact that we have to deal with patients with this disease in fairly large numbers, we have been interested in arraying these factors, in order that we might do everything possible to offset them.

It is unfortunate that hyperthyroidism—and I speak of exophthalmic goiter and toxic adenomata as both under the one head of hyperthyroidism, as I believe that they are one and the same disease—can be and is present so often for a long time without greatly interfering with the patient's activity. This results in delay in diagnosis and delay in treatment,—one of the main factors that produces mortality in hyperthyroidism. Only very rarely does hyperthyroidism appear suddenly, as after a marked emotional strain or shock. The common course of the disease is to appear very gradually and to show very gradual intensification until it has become fully developed. After the disease has become fully developed and the average ambulant pulse rate is 120 or 130 or over this, sudden changes in the disease are possible and not uncommon.

We have no very tangible way whereby we can measure and demonstrate the effect of prolonged toxicity upon the organism, but we do know that in our operative results the highest mortality is in those patients who have had the disease a long time,—a year or over. In fourteen seemingly avoidable deaths out of an unselected operated group of 2,769 patients with toxic goiter analyzed in our Clinic by Dr. H. M. Clute, the disease had been present for over a year, and in all except four had been present for over two years. In this operated group of 2,769 toxic patients there were no deaths in patients who had had the disease a year or less. This factor should, then, always be arrayed before one's mind when patients are carried through long periods of indecisive methods of treatment for this disease.

Age is likewise a serious factor in the mortality of hyperthyroidism. People from the later part of middle age onward who develop hyperthyroidism are in general much more serious problems than are the younger people with more obviously intense states of the disease. In this same group of fourteen avoidable deaths, but two of the patients were under forty years of age, the average age in the remainder being fifty years. One cannot, as stated above, accurately compute the ill effects of prolonged thyroidism on the organism, but it seems evident that the disease causes a constant and unavoidable energy wastage, which can be compensated for in the youthful with plenty of reserve, but results in breakdown, often first prominently evidencing itself by auricular fibrillation, in the middle-aged and elderly, in whom reserve has been at least in

some measure exhausted by work, disease, and merely years of living. One should, therefore, realize that patients with hyperthyroidism, roughly of forty years and over, should be considered as falling into the group with an added mortality factor.

A very obvious indication of the seriousness of hyperthyroidism is weight loss. Weight balance in hyperthyroidism is roughly dependent upon two things,—(1) the degree of increased combustion, and (2) the ability of the individual to compensate for this hypercombustion by an increased food intake. Out of these fourteen supposedly avoidable deaths in 2,769 operated toxic goiter cases, the weight loss in nine cases in which it was known averaged 45 pounds. Patients showing considerable weight loss must therefore be considered as possessing a very definite mortality factor. There are two features to be appreciated about weight loss in hyperthyroidism: (1) that even though the weight be kept somewhere nearly in balance by excessive food intake, nevertheless its reduction into stored weight takes place only at the expense of excessive combustion processes on the part of the organism, and (2) likewise that when weight loss is not compensated for by food intake, the effects of hypercombustion are most evident in the form of great weight loss, which must, even though not demonstrable, produce at least an undesirable effect upon all of the structures of the body.

Patients with marked weight loss must therefore be considered as possessing a serious mortality factor, and its occurrence must be considered as an indication that active measures to check the disease should be undertaken.

Basal metabolism reports are not dependable criteria of the seriousness of the degree or type of thyroid toxicity. In general, the degree to which the basal metabolism is elevated will correspond approximately to the intensity of the disease, but disturbing inaccuracies in the relationship between basal rates and serious states of hyperthyroidism are not rarely, but quite frequently, arising. We have, for example, seen a young man with a basal metabolism rate of +120 pass into a thyroid crisis, and in just the same manner we have seen a more elderly individual with a basal rate of +38 pass into a thyroid crisis. Likewise we have constantly a number of patients with basal metabolism rates as high as +85 to 100 or over who pass safely through subtotal thyroidectomy, and some patients with low rates who do not. In the fourteen supposedly preventable deaths in the 2,769 operated patients with toxic goiter, the average basal metabolism rate was +55, but there was one of +30, one of +34, and one of +36. While, in general, high basal rates may be viewed as possible mortality factors, this must not be construed into the not uncommon position that rates as high as +100 and over are a contraindication for operative procedures. No basal metabolism, no matter how high, possesses in itself sufficient value as a mortality factor to solely constitute a contraindication to surgery.

Just as high basal rates are not a contraindication to surgical procedures, so, on the other hand, low rates are no guarantee that the patient with thyroidism is either in a safe stage of the disease or to be considered a safe operative risk. I spoke before this assembly last year about the apathetic type of thyroidism characterized by relatively low basal rates, by relatively moderate tachycardia, by apathy rather than activation, by relatively little active reaction to stress such as operative procedures.

Apathetic thyroidism is quite contrary to the commonly accepted picture of thyroidism in the form of typical activated thyroidism which is so characteristically accompanied by very obvious danger signals, such as flushed skin, generalized over-activation, rapid heart (140 and over), full, bounding pulse, tumultuous heart action, and emotional excitability. This is the typical and well-known type of thyroidism.

One should have in mind how misleading the atypical apathetic thyroidism may be, and realize that with its low basal rates, its non-activation and its unstriking pulse character, it may well lure one into a feeling of false security which can result in a fatality through failure to realize the serious possibilities in patients with thyroidism of this type.

For a great many years it has been suggested that the thyroid has something to do with the neutralization of the toxins of infection. There is no real evidence at hand to bear out this assumption. Changes in the microscopic findings within the gland when associated with infection have been reported by Cole and Womack, but we, in a series now of 8900 operated goiters, have not been impressed with the fact that infection is any more or less common in patients either with hyperthyroidism or myxedema. We are, however, constantly being impressed with the fact that the occurrence of a severe infection in a patient with hyperthyroidism very quickly and definitely produces an intensification of the hyperthyroidism and constitutes in itself a serious mortality factor with real possibilities of a fatality. I know of nothing which can so quickly (in a day or two) change hyperthyroidism of moderate degree to one of dangerous intensity bordering or passing into an acute crisis, with delirum, vomiting, uncontrollable activation and uncountable pulse rate, as a super-imposed infection, the most common occurrence of which is in the form of follicular tonsillitis. Not infrequently we have seen patients who were up and about, with basal metabolism rates of +35 to +45, with moderate pulse rates, with little or no weight loss, suddenly changed to wildly intoxicated individuals by the

effect of an acute infection. One should realize, then, that infection constitutes a real mortality factor in hyperthyroidism. It demands immediate attention toward the infection in the way of drainage, which unfortunately is rarely possible for several days, if at all. During this time, the situation frequently becomes serious, and emergency measures directed particularly toward the intensified hyperthyroidism must be instituted. The most important of emergency measures are the intravenous administration of fluids and glucose, providing thus the two essential elements for consumption in hypercombustion, the utilization of which doubtless saves the organism from consumption of its own fluids and fuel so necessary for maintenance of ordinary bodily function.

So striking are the reactions of the organism to the effects of high basal rates, particularly in young people, and so immediate is the relief afforded by the introduction of fluids and glucose, both readily available for combustion, that the notion that they protect by providing fuel for the flames in place of fuel from the patient's own organism cannot be avoided.

Pregnancy has always been viewed as a serious complication of hyperthyroidism, and it must be admitted that if permitted to go to full term and the labor is difficult, prolonged, and necessitates the employment of a general anesthetic during a very active stage of hyperthyroidism, it does definitely represent a very serious mortality factor in the management of hyperthyroidism.

We have had it impressed upon us that the administration of a general anesthetic and the undertaking of any procedure of the magnitude of a major operation, exclusive of one directed at the thyroid, will result in a fatality in many of the cases. We have seen deaths from thyroidism following appendectomy, following cholecystostomy, following perineorraphy, and we are so fearful of any operative procedure, other than a thyroid operation, on patients with active hyperthyroidism, that we urge against even tonsillectomy or tooth extraction with an anesthetic in patients with well-developed states of hyperthyroidism. We are so impressed, in patients with this disease, with the possibilities of serious thyroid reactions to non-surgical procedures, that we urge that the thyroid operation always be undertaken first, and that any general surgical operation be deferred, if possible, for at least six months.

From the foregoing remarks, it is evident that we consider that permitting pregnancy to go on to full term in a patient with severe hyperthyroidism provides, in our opinion, a very serious mortality factor. It is at once evident that the avoidance of this undesirable factor can be accomplished in one of two ways: (1) by interruption of pregnancy, or (2) by operation upon the thyroid, and the latter course is by far the more satisfactory to pursue. Interruption of labor, if early, may be accomplished safely, but leaves the patient still with the hyperthyroidism. If, on the other hand, infection occurs, then the hyperthyroidism becomes a serious and at times a dangerous problem.

Interruption of gestation late in pregnancy is a procedure of sufficient magnitude to constitute a risk approaching that of full term labor and delivery.

In a consecutive series of 3,678 patients operated upon in our Clinic for toxic goiter, there were fifteen patients who had toxic goiter and pregnancy,—the incidence being thus 0.41 per cent. Thirteen of these patients had exophthalmic goiter and two had toxic adenomata. There were no deaths. One mother miscarried two days after a long automobile ride to her home eight days after operation, and normal deliveries with normal children occurred in the remaining group of mothers. It seems evident, then, that subtotal thyroidectomy in the presence of pregnancy is not a dangerous procedure, and that the danger of miscarriage following subtotal thyroidectomy is not unduly great.

We strongly urge, then, that the association of pregnancy with thyroidism is distinctly a mortality factor when pregnancy is permitted to advance up to later stages, and that this mortality factor can be avoided without undue risk to the mother or to the pregnancy by early subtotal thyroidectomy before this mortality factor is well developed.

Conclusions

Patients with long standing thyroidism, a year or over, possess a very definite mortality factor.

Patients with marked weight loss likewise possess a definite mortality factor.

Basal metabolism rates are not dependable criteria as related to a mortality factor.

Acute infection in the presence of hyperthyroidism is a definite and dangerous mortality factor.

Pregnancy in its early stages is not a serious mortality factor, but the latter stages of pregnancy with full or nearly full term delivery constitutes a real mortality factor in well-developed hyperthyroidism.

Subtotal thyroidectomy in hyperthyroidism associated with pregnancy can be done with little danger either to the mother or child, and is the safest and best way of avoiding and dealing with this factor.

THE TREATMENT OF FUNCTIONAL GASTRO-ENTEROLOGICAL DISTURBANCES

By L. PULSIFER, M.D., ROCHESTER, N. Y.

AS an internist who is especially interested in gastro-enterology I find that about sixty per cent of the patients who come to me do so because of functional disorders of the gastro-intestinal tract. Most of these patients have consulted several physicians and, as a rule, have not been very successfully nor, I may say, understandingly treated. To be sure among them will occasionally be a hopeless psychoneurotic or a mentally deranged individual but by far the majority of these patients seem to respond to treatment in a most satisfying manner. It is unfortunate that medical textbooks do not often contain any comprehensive outline for guidance of the neophyte who finds himself confronted with the problem of treating a functional "dyspeptic." I have no delusions that I am offering anything new. However, in an effort to supply such an outline, and with the hope of stimulating a more general interest in the thoughtful treatment of this large class of patients, I will submit the following.

The symptoms complained of are those caused by: Overactivity (principally pain, spastic constipation, diarrhea, and maldigestion with resulting flatulence), and those explainable on the basis of reverse activity (principally fullness, belching, nausea, vomiting, and "bilious" spells).

The findings usually include some of the following: Diffuse abdominal tenderness, tenderness confined to parts of the colon, distension, tympany; and stools which may be tiny caliber, lumpy, mushy, watery, sour, filled with bubbles, or undigested food.

Organic disease in the background may be found at the start, may or may not be suspected, or if present, may become clearly apparent only when those signs and symptoms which are on purely functional basis have been quieted down so that they no longer confuse the picture. The following is a list of those more common organic conditions which one must keep constantly in mind when treating what may seem to be disordered function: Teeth (insufficient for mastication), painful hemorrhoids or anal fissure, diverticultis, appendicitis, gall-duct disease, malignancy, ulcerative colitis, peptic ulcer, coronary disease, pregnancy, nephritis, or other kidney conditions, tuberculosis, tabetic crisis, and migrain.

The status of the *patient's nervous system* and his manner of living must be thoughtfully considered and the question asked, "put in his shoes could I be well or feel well?" Is the mental endowment adequate? Has he migrain, epilepsy, feeble-mindedness, or insanity? Are there acquired neurotic tendencies? What of his upbringing? How does he fit into society? Is he reliable? What of his family and sex life? What stress does he work under? What is the significance of his illness to him, and what of his state of mind? Has he fears, worries, and economic burdens? What of his habits and manner of living? Does he sleep sufficiently? Does he have leisure? Does he smoke or drink? Does he have natural bowel function or does he take physics and enemas? What of his diet? Does he eat wisely, regularly, sufficiently, or too much? Does he bolt his food? Outline a typical day.

One must listen patiently and sympathetically being always kind. He must be naturally interested in the problems of people and must adopt a manner in dealing with the patient that gives positive assurance that he knows what he is about. Often it will take several sessions before the actual facts involved in a definite emotional stress will come to light.

The *examination* must be reasonably adequate to minimize the chance of missing organic diseases and at the same time to impress the patient.

The treatment is first psychic, is closely bound up with the relation between physician and patient, and is largely suggestion. Many of those physicians who believe they get such good results with this diet, medication, or course of treatment, I believe do get good results. However, I am of the opinion that it is not because of their pills nor their diets, but even in spite of their medication, and indigestible diets they may often (with their fine personalities) suggest disturbed minds back into tranquillity and the functional disturbances into oblivion. A determined effort should be made also to remove sources of emotional stress.

Watching always for organic disease in the background, one should next try to give *sympto matic relief.* This may greatly contribute toward getting proper hold on the patient and so encourage him. To this end the following agents are valuable:

Sedatives—usually in small doses over a con siderable time.

Bromide is most often use.d It is surprising how frequently five or eight grains three times a day will relieve distress due to spasm, quiet excessive activity, and overcome spastic constipation. Nervous vomiting may usually be controlled by sixty grains per rectum every eight hours if food by mouth is withheld and adequate liquids given other than by mouth. Luminal sometimes alone and sometimes in combination with bromides in doses of one-eighth to one grain, may be valuable. It is especially effective in preventing and ameliorating migrain disturbances.

Analgesics—such as antipyrene, phenacetine, and the salicylates may give relief from mild degrees of intestinal discomfort.

Antispasmodics—are best used in conjunction with the sedatives, but when used alone may benefit most those patients who are quite stable emotionally. Atropine sulphate, one two-hundredth of a grain for distress due to spasm, or one five-hundredth three or four times a day is very convenient. Tincture of Belladonna, six to ten minims three or four times a day and tincture of hyoscyamus in similar doses are useful.

To promote downward peristalsis: Calomel is very worth while especially in that type of reverse activity designated as biliousness." Doses of one-tenth grain at half hour intervals for four to eight doses will rarely need to be exceeded.

Magnesium Carbonate in doses of two to eight grains taken a little while after eating will often eliminate "heart burn," "crowding," and regurgitation.

Disodium phosphate, four to twelve grains, will occasionally do likewise, and when given an hour before meals may help to stimulate the appetite especially if taken with hot water. This later effect seems to be augmented if bromide is given at the same time.

Calminatives are occasionally of some value.

To slow down overactivity: Opium derivatives are most efficacious. Powdered chalk in teaspoonful doses will often be sufficient, especially in fermentative diarrhea. Tribasic calcium phosphate, and bismuth are of similar value.

Hot packs, electric pads, and hot water bottles are most excellent agents to quiet spasm and aid in the control of pain and diarrhea.

To regain habits of restful sleep, hypnotics are invaluable: Barmidon, Allonal, or Adalin, I have found most satisfactory. Chloral will sometimes serve when others do not. The effect of Luminal too often extends into the next day.

Rest, a few minutes before meals, will be very often a desirable aid toward improvement of the quality of digestion. Of course a placid, happy mental state during meals is to be cultivated. This last is of vital importance. Extra periods of rest during the day may often enable one to store up reserve emotional stability.

The diet should be adequate and, in general, low in laxative quality. Constipation per se will perhaps be more quickly overcome if considerable bulky but chemically bland vegetables are used.

If pain, or distress, or diarrhea is the major complaint at first it will be wise to make the diet almost residue-free, adding bland residue as these symptoms subside. If considerable whole food is found in the stools the "Smooth" diet plan had better be adopted.

In the case of starch indigestion only the more easily digested starches had better be used (such as fine ground cereals and toasted bread), the residue should be restricted at the start, and cream, butter and protein foods should be depended upon for nourishment.

In cases of persistent nervous vomiting everything by mouth may wisely be withheld while fluids are given in other ways, and sedatives by bowel, until the vomiting is under control, then gradually dry foods in small quantities may be taken.

Coffee, much tea, stimulants, and over-smoking had better be avoided.

Increased calories for the malnourished, decreased for the heavy.

Quite often five or six small meals a day will be better tolerated than will three large ones.

Habits of regular eating, and of regular bowel elimination, and methods of induction of normal bowel movements should be taught, *i.e.,* oil enemas to be retained over night, suppositories and small plain water enemas. It should always be the aim to cultivate spontaneous evacuation and methods of induction of defecation should be withdrawn as promptly as possible. Colonic lavages probably definitely postpone the time when normal habitual elimination can be accomplished. They had better be avoided. Leisure of a real kind should be obtained wherever possible with time arranged for work, fun, rest, and exercise.

The prognosis in such cases depends of course primarily upon how fixed in the patient's make-up the abnormal function has become: and almost to an equal degree upon how well the physician understands the true nature of the situation and then can apply the elements of therapy and keep at it, stressing those which affect more particularly the individual problem. Most of these patients improve right soon. Many may relapse temporarily unless followed when a considerable degree of semi-improvement is the rule.

CONCLUSIONS

1. In general, functional gastro-intestinal disturbances are not understandingly nor adequately treated.

2. Organic disease, one must constantly watch for, but the patient should not be allowed to feel uncertainty.

3. The mental status of the patient should be studied, and emotional stress relieved wherever possible.

4. Reinforcement should be given in the form of suggestion and symptomatic relief.

5. The manner of living, eating, and diet, and bowel management should be adjusted according to common sense standards. Catharties and irrigations should be avoided.

6. The patient should be followed and a general plan of treatment persisted in. Improvement is the rule.

PREVENTION OF INJURY TO RECURRENT LARYNGEAL NERVES DURING THYROIDECTOMY*

By ALFRED H. NOEHREN, M.D., BUFFALO, N. Y.

THYROIDECTOMY, if done according to modern methods, is today one of the safest operations in surgery. In no other field of surgery has greater progress been made. Mortality has been reduced to the vanishing point until in most conditions in which thyroidectomy is indicated, the hazard of operation is much less than the hazard of the disease under non-operative treatment or no treatment at all.

Operative and post-operative complications have also been greatly reduced. Hemorrhage, thyroid storm, and tetany are very rare. The one dreaded complication that still remains today is injury to the recurrent laryngeal nerves with its resultant change or loss of voice and difficulty in breathing. Here there is still room for improvement.

It is difficult to determine the actual percentage of nerve injuries, as few statistics are published. Those reported vary all the way up to 42 per cent.[1] Before Mikulicz emphasized the importance of leaving some thyroid tissue behind, Billroth reported paralysis of vocal cords following thyroidectomy in 32 per cent of cases, Jankowski in 44 per cent. After following the suggestion of Mikulicz, Kocher reported a series of 900 thyroidectomies with only 7 per cent injuries.[2] Among recent statistics, Fowler and Hanson found injury in from 1 to 14 per cent. In our last 100 thyroidectomies, careful pre-operative and post-operative laryngeal examination showed that there was some laryngeal paralysis in two cases before operation and in six cases after operation. In only one of these, a very large bilateral nodular intrathoracic goiter with marked pressure on the trachea, was there complete loss of voice or respiratory difficulty. The other five had only slight temporary trouble and today have a perfect voice and no respiratory difficulty.

In reviewing the technique of thyroidectomy with a view to still further reduce the number of recurrent nerve injuries, we have come to the conclusion that the common practice of sewing over the thyroid stump by drawing the lateral capsule over to the pretracheal fascia must at times cause tension or pressure of the nerve.

The recurrent laryngeal nerve, being a non-medullated nerve, is exceedingly sensitive to pressure or traction. It is tucked away behind the thyroid lobe opposite the cleft between the trachea and esophagus. It has often been described by some anatomists (Cunningham, Deaver), as being behind the capsule of the gland (Fig. I.) and that therefore any manipulation anterior to or within that capsule is safe. (Fig. II). It has also been thought that any traction on the lateral capsule pulls the lobe away from the nerve and therefore is safe. (Fig. III). Others (Treves, de Quervain, Gray) have described the capsule as leaving the thyroid gland at the postero-lateral portion of its lobe and going directly backward to the prevertebral fascia, leaving the posterior surface of the thyroid lobe uncovered and in direct contact with the nerve. (Fig. IV.) Lately, Fowler and Hanson have reported that in 200 cadavers examined by them they have found this latter condition in practically every case. In 29 cadavers examined at the University of Buffalo Medical School, we found that in every case where a definite pretracheal fascia could be demonstrated, it left the gland at its postero-lateral surface and joined the prevertebral fascia behind the recurrent laryngeal nerve, thus surrounding in one sheath thyroid gland, trachea, esophagus and recurrent laryngeal nerves.

It is true that there is a very thin transparent fascia surrounding the thyroid gland, the so-called true capsule; but the surgical capsule, the one that is used to anchor sutures when the thyroid tissue itself will not hold a stitch and that is used to fold over the stump, goes back to the prevertebral fascia as described above.

If this, then, is the true anatomy of this region, it naturally follows that when the lateral capsule is drawn over to the midline by suturing it to the pretracheal fascia or to the capsule of the other side it does not pull the remnant of the thyroid away from the nerve, as formerly thought, (Fig. III.) but compresses the thyroid tissue against the nerve. (Fig. V.) This is especially true if the gap between divided fascia and midline is so great or the tissues so adherent that considerable tension is necessary. In cases of persistent oozing, sewing over the stump is the easiest way of controlling it. If this can be done without tension, it may be done with safety, but when there is tension, it is better to place a small iodoform gauze pack over the oozing surface. This can be removed in 24 hours without trouble.

It may be objected that the leaving of a raw surface is bad surgery, causing more absorption of toxic secretion and greater scar formation later on. This, however, is not true, for this surface is immediately covered and protected by the ribbon muscles when these are accurately sewed together. (Fig. VI.) This causes less scar formation in the interior of the gland substance and less absorption of secretion than when the whole mass is compressed and any secretion forced into the circulation.

While local anesthesia is a great aid in preventing injury to the recurrent laryngeal nerve by allowing constant testing of the voice, general

* From the Buffalo Thyroid Clinic.

anesthesia by a skillful anesthetist is now so safe and pleasant that in the ordinary case it is preferred and both the patient and the surgeon spared a great deal of strain. In large adenomatous goiters, especially of the substernal type, this added measure of safety given by local anesthesia should be used. But even in general anesthesia the voice can be tested during the operation.

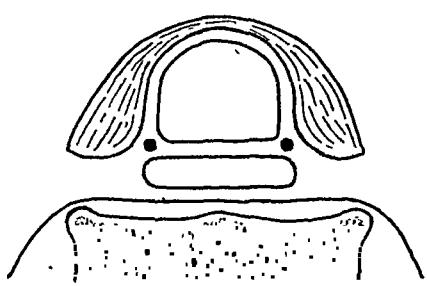

FIGURE 2

Relations after a typical subtotal thyroidectomy. If figure 1 were correct, this nerve would lie behind capsule, safe from any manipulation of thyroid substance in front of capsule.

After trying various methods, we have now adopted the following routine: Three hours before operation, the patient is given from five to ten grains of luminal, as suggested by Bartlett.[4] This relieves the patient of the strain of anticipation while waiting to go to the operating room, makes her less conscious of the trip to the operating room, and greatly reduces the amount of general anesthetic necessary to begin the operation. After the skin incision has been made, the field is injected with one-half per cent Novocain. By making the injection after the flaps have been made, the numerous punctures of the skin with their possibility of infection are avoided

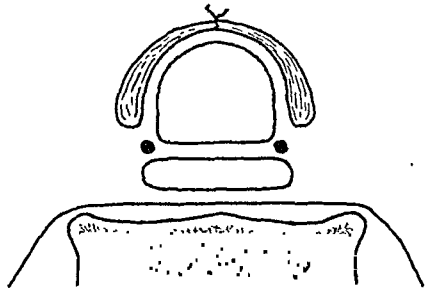

FIGURE 3

If figure 1 were correct, the folding of thyroid remnant to midline pulls it away from the nerve and out of harm's way.

and there is less danger of injecting into the visualized veins. This injection allows still greater reduction of the general anesthetic. After one side has been completed, the patient is allowed to come out of the anesthetic sufficiently to answer

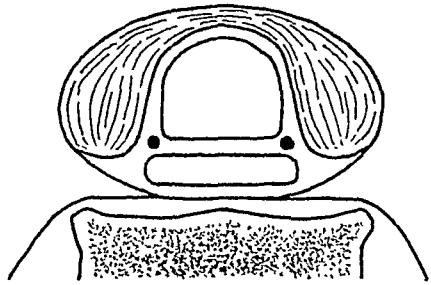

FIGURE 4

Actual relations of recurrent laryngeal nerve. Thyroid capsule leaves side of gland and goes back to prevertebral fascia, leaving posterior surface of gland bare and in direct contact with nerve.

questions. The patient seems to answer reflexly or subconsciously and it is surprising how easily the voice can thus be tested without waking the patient completely or delaying the operation. The operation is then completed under a very light general anesthesia. Thus, by assuring ourselves

after one lobe is removed that the voice is unchanged, we have absolutely protected ourselves from causing injury to both recurrent nerves.

Injury to one nerve is bad enough, but its effect on the voice is only temporary until the cord on the other side compensates for the deficiency of its mate. But injury to both nerves is a tragedy and must be made impossible to make thyroidectomy a justifiable procedure.

But not only does this method prevent bilateral injury, but unilateral as well, for in a difficult case or one where it is necessary to work close

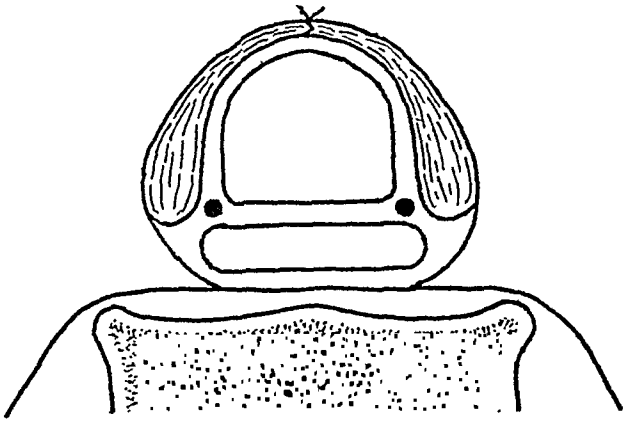

FIGURE 5

Folding over of thyroid remnant tends to compress it against the nerve.

to the nerve, the patient can be kept in more or less continuous conversation, as suggested by Richter.[5]

While voice-testing insures against immediate injury to the nerve, it does not guarantee against later injury by scar formation. It is, therefore, necessary that all the details of technique to prevent scar formation, so well described by Crile,[6] be observed and that suturing of the stumps, as indicated in the beginning of this article, be done, if at all, carefully and advisedly.

CONCLUSIONS

In addition to the many safeguards already described and carried out in the technique of thyroidectomy to prevent injury to the recurrent laryngeal nerves, we would add the following:

1. The postero-internal portion of the thyroid lobe left behind in thyroidectomy should not be disturbed by folding the raw surface over on

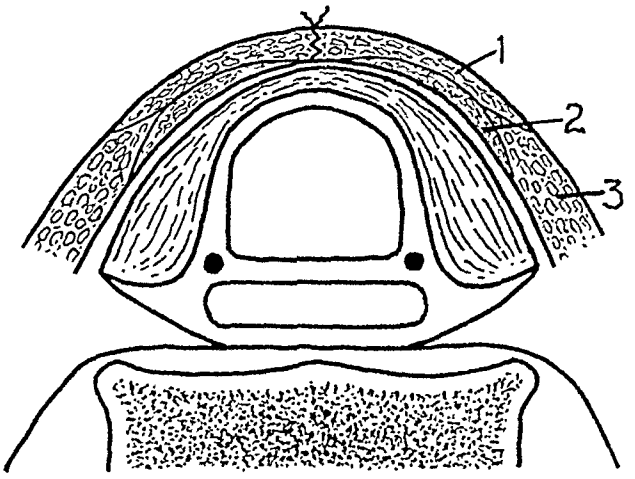

FIGURE 6

Raw surface of thyroid remnant covered by ribbon muscles, preventing compression of remnant and extensive scar formation.

Ribbon Muscles.

2. *Sterno-Hyoid.*
3. *Sterno-C-Mastoid.*

itself. This is not necessary in most cases and is apt to compress the nerve.

2. Removal of the second lobe in thyroidectomy should not be undertaken until convinced that the nerve on the opposite side has not been injured by removal of the first lobe. A method of insuring this result is described.

LUNG CANCER AND LUNG TUBERCULOSIS

By H. T. PESSAR, M.D., NEW YORK, N. Y.

THAT lung cancers are apparently increasing in frequency is generally conceded. While older statistics indicate that primary lung cancers represent only one per cent of all primary cancerous growths, recent authentic data disclose an increase as high as 10.0 to 15.0 per cent.

It is to the credit of the clinician that primary lung cancers are now recognized ante mortem with precision. The tuberculosis campaign carried on in all civilized countries undoubtedly contributed no small share to our present clinical knowledge of primary lung cancers, enabling us to recognize this disease in its comparatively early stages; for, by his efforts directed primarily to the aim of ruling out pulmonary tuberculosis, the clinician is necessarily led to other chronic pulmonary diseases, of which cancer is assuming greater and greater significance. The point is well illustrated by the following case report from the records of the Mott Haven Tuberculosis Clinic:

A male patient, 50 years of age, was referred to the Clinic on September 16, 1930, for placement in a tuberculosis institution. He told the following story:

He was apparently in good health up to June of the same year, when he began to have pain in the right side of the chest, cough, bloody expectoration, and afternoon temperatures. For the last three weeks he has been feeling very weak and quite ill so that he is hardly able to stand up. His past history, with the exception of gonorrhea and drug addiction, was negative.

Pulmonary tuberculosis might well be the cause of his complaints.

Physical examination: Pulse 126, Temp. 101 (mouth), Resp. 28. Enlarged glands in the axillae. Deep and superficial glands of the neck were found to be enlarged and hard to the touch. Lungs: Dullness to flatness from third rib to base anteriorly on the right side. Respiratory murmur greatly diminished, to absence, in this area, but exaggerated in the upper part above the area of dullness. The physical findings suggested either a tumor mass in the right lung or an interlobar incapsulation of pus. His blood showed a secondary anemia and a negative Wassermann. His sputum was negative. *X*-ray revealed a mass at the hilum extending outward and invading the right pulmonic field, with infiltration towards the periphery.

We made a tentative diagnosis of primary bronchogenic carcinoma, and had the patient admitted to the Cancer Hospital on Welfare Island. Our provisional diagnosis was confirmed, and the patient was immediately put on intensive, deep *x*-ray therapy.

No important developments have taken place in three months. The patient is still alive. The enlarged superficial and deep cervical glands have entirely disappeared under deep *x*-ray therapy. His persistent cough and pain have diminished. There is good reason to believe, judging from the present appearance of Roentgengrams, that the tumor has also diminished in size.

COMMENTS

1. It is not a matter of common knowledge that afternoon rise of temperature, so much stressed in pulmonary tuberculosis, is present in a very large percentage of lung malignancy. The rise in temperature is caused by:

(a) Toxic absorption from degenerated tumor cells.
(b) Infection of the tumor mass.
(c) Absorption from dilated bronchi distal to the obstructing tumor.

2. Blood spitting, while most common in phthisis, occurs in many other chronic lung diseases, and is often seen in bronchiectasis, and not infrequently in chronic bronchitis. A possible malignant etiology should be excluded *when it occurs for the first time* in an individual past middle age.

3. Severe, prolonged pain in the chest is not common in lung tuberculosis uncomplicated by pleurisy, but it is an early persistent symptom in neoplasm of the lung. Its occurrence in an individual past 45 years of age, should put the alert physician on his guard.

4. An impressive feature of the disease is the absence of symptoms in the beginning, markedly contrasted by the occurrence of great prostration later, out of proportion to the amount of involvement.

5. The *x*-ray findings in bronchogenic hilar neoplasm are definite and characteristic—the dense mass at the hilum with infiltration towards the periphery. The infiltration may be actual or due to atelectasis distal to a stenosed bronchus.

6. Since 90% of all primary neoplasms of the lungs are bronchogenic, a change in the intensity of breath sounds is an early and important sign of pulmonary carcinoma. Diminished intensity of breathing *in one lung* in an individual of cancer age calls for a bronchoscopic examination to rule out malignancy.

7. Definite diagnosis is imperative, because prognosis at present is grave; and the only hope for prolongation of life and perhaps cure, lies in early diagnosis followed promptly by intensive deep *x*-ray therapy. This is generally accepted as the best and most conservative form of treatment where applicable.

LEGISLATION

This issue of the Journal will probably be the last one before the Legislature adjourns. One can never be sure what will happen until the law-makers have actually closed their session. The bill sponsored by the Governor's Health Commission was introduced during the middle of the session, and was at once subjected to amendments with the consent of its proponents.

The Osteopathic bill seems to have been defeated in the Assembly, but the fate of the other cult bills seems to be in doubt, owing largely to the habit of legislators to appear to agree with persistent petitioners while expecting the Governor to veto their bills. However the law-makers show an increasing indication to give heed to the advice of the State Medical Society.

PRESIDENTIAL COMMENTS ON CURRENT EVENTS—NO 19

Organized medicine has directed public medical thought in this state for one hundred twenty-five years The initiation of the efforts of medicine to meet its own problems and its public relationships problems furnish some of the finest examples of leadership to be found anywhere Just as today, efforts to initiate advances in the past met with some opposition This is a natural and desirable condition because out of it comes the truth

When the bill to incorporate medical societies in the State of New York was before the Legislature in 1806, it had to contend with powerful opposition because it was feared that the tranquility of the state would be disturbed by the organization of forty incorporated groups of physicians" It was finally shown however that it would "benefit the science of medicine the profession of medicine, and the public, and after the enactment the advances came in the science and relationships of medicine

The health bill before the Legislature now has been the subject of many conferences between the groups who would be responsible for its administration or affected by its provisions It has had the same tests applied that the Public Relations Committee uses to reach its conclusions and now it represents a composite opinion, only with doubt as to its major provision whether general conditions are yet favorable for its enactment

The county health unit was advocated by the Commission primarily in order to enable the smaller and less well to do counties to provide themselves, with state aid, with an effective health service, along the lines mainly of public health nursing, laboratory provision, and clinics for needed purposes If the degree of education regarding county health units is not sufficient and if the capacity of the state to provide enough trained personnel is not sufficient and if too much work is to be suddenly thrust upon county medical societies to set up an effective health organization, then it would be better for this provision to have another year of study

The great substantial provision for tuberculosis has developed no adverse opinion Even in this period of economic depression, confidence is so great in the minds of people that they seem to be willing to appropriate seven hundred fifty thousand dollars to build one district hospital and to buy three sites for the three districts This proposal indicates the greatest progress in any one year since 1909 when the permissive county tuberculosis bill was passed The primary purpose of these three additional hospitals is to bring service to rural counties which are too small to have service of their own The ready acceptance of this somewhat unexpected and novel proposal of three additional state tuberculosis hospitals is a striking evidence of the great impression made on the public opinion of the state by the tuberculosis movement and of the general high standing of the county tuberculosis hospitals The hospital work in tuberculosis is in a virgin field with no preconceived conception of method and it is easier to advance under such conditions that it is in other fields where methods mean a change of old habits and old customs

All other provisions of the bill have been amended to the satisfaction of all interests and particularly to the organized medical profession

The problems of medicine should be solved by the medical profession Continued study and conference will arrive at correct conclusions It took ten years of effort to organize medicine in the state for the benefit of its science and to protect the interests of the public The result is that medical societies became the outstanding influence on the science of medicine, the outstanding influence in protection of the public from imposition of those who assumed the title of doctor, the outstanding influence on public health

In November, 1930, at the annual meeting of the Secretaries of the Constituent State Medical Association, the President of the New York State Society said in a paper on "Public Relations" that "organized medicine can never overcome its troubles without the aid of some greater degree of self appraisal as to whether it is meeting all of its obligations of public service If it does not meet these obligations some other agency will do so just as has been done in other countries This will quite likely be the action of the state and may not be to the satisfaction of the profession The medical profession has two ways open to it One is to fight public opinion and to retreat as slowly as possible The other is to accept the practical philosophy of self appraisal If the result of such self examination warrants it, let organized medicine make proposals to meet the needs of public health organization for its administration and proposal of how to provide adequate medical care when sickness comes This can be approached by a study of relationships and a willingness to cooperate with other agencies, under the expert guidance of the profession of medicine Are we willing to undertake the responsibility of such a study? Self appraisal of our own organization and proposals from our own organization to meet the great problems of health and sickness service will put the profession of medicine in the position that it should be in and in the position that the public expects it to occupy"

WILLIAM H ROSS

CONFERENCE OF COUNTY SOCIETIES IN MICHIGAN

The March issue of the Journal of the Michigan State Medical Society is packed full of interest in all its 132 pages of reading matter. Of special value are the minutes of a meeting of the Council covering 19 pages, and the 32-page stenographic report of the Annual Conference of County Secretaries.

The topics discussed in the Conference were unusually practical, and were presented in a remarkably clear manner, and many are abstracted in this Journal in the department "Our Neighbors," beginning on page 438. The program was as follows:

1. "The Public Relations of Physicians," by Dr. B. R. Cobus, Chairman of the Council.
2. "Medico-Legal Defense," by Dr. Frank B. Tibbals, Chairman of the Medical Defense Committee.
3. "The Trend of Medicine," by Dr. Nathan Sinai, Ann Arbor.
4. "Organization Problems," by Dr. C. W. Waggoner, President Ohio State Medical Society, Toledo.
5. "Important Factors in Operating a County Medical Society," by Dr. Philip Riley, Jackson.

These topics were presented in the form of papers whose importance would have justified their being listed in the index; but since they are not so listed, they will be overlooked by many readers.

It is the policy of the NEW YORK STATE JOURNAL OF MEDICINE to list every article in the index, so that it will catch the eye of the casual reader. Even the news items are listed; if an item is not worthy of a place in the index, it has no permanent value, and therefore should not be printed.

A medical historian or philosopher, wishing to discuss modern trends of medicine and the activities of the medical societies of the states and counties, will have difficulty in discovering his facts, for they are scattered through news items and reports of conferences and meetings. The NEW YORK STATE JOURNAL OF MEDICINE has endeavored to record the current activities of medical societies in two departments:

1. "News Notes," containing the records of the Medical Society of New York State and its constituent county societies.
2. "Our Neighbors," consisting of abstracts from the Journals of other State Societies.

Each item in the two departments is given a double column heading, and is listed in the index.

The size and value of these two departments may be judged by the fact that their annual index filled six pages of the Journal, and contained upward of 1,200 references. This is probably the most extensive of all the bibliographies of current activities of the medical societies of the States and Counties.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

The Interne: Twenty-five years ago medical graduates did not find interneships as available as at present; and there was often a question regarding the necessity of a term of hospital service. An editorial in this Journal of April, 1906, ascribes the value of an interneship to the man himself, and says:

"Now is the season when the student about to graduate in medicine casts his covetous eye around for the hospital whose cangenial walls shall receive him and harbor him for some two years, while he pursues the work which he hopes will culminate in the making of a doctor. He is fortunate, indeed, if he rids himself of the idea that he is after a hospital; he is wise if he is imbued with the thought that he is seeking knowledge and experience. There will be classmates of his who, without becoming internes, will excel him in both of these. The interneship is but an opportunity; there are many others. The earnestness and the fidelity and the thoroughness that he puts in his study tell the story. He can get out of his cases only the knowledge that he works out of them. There is no easy-chair method. Scientific knowledge must be worked for; it is never a gratuity. So let the student try for his interneship: he is fortunate if he gets it—fortunate for the opportunities which it affords. Happy is he if his college has taught him enough of a subject to whet his appetite for more.

"It is not the college, it is not the hospital. It is the animus within the man that shall make him superior. If he has the thirst for knowledge, he shall have it; if he has the longing to perfect himself he shall excel. We have pretty much what we desire: provided always that we are worthy and capable. There is many a country practitioner—who once had the advantages of the help and sympathy of a good preceptor—who carefully studies his cases, thinks about them, reads about them, compares them with previous cases, who is above ready-made diagnoses and ready-made prescriptions,—who is in his art and science a peer, and in his community the well-beloved physician and the noblest type of a well-rounded man."

MEDICAL PROGRESS

Diathermy Treatment of Nephritis.—W. Ewig, in an article in the *Deutsche medizinische Wochenschrift* of January 9, 1931, says that diathermy applied to normal kidneys is followed by marked diuresis, promoting excretion not only of water but also of sodium chloride and nitrogenous substances. Extraordinarily good results from this treatment have been observed in acute glomerulonephritis. Two illustrative cases are described. One of these was in a girl of 13 in uremic coma, with blood pressure 193 mm. Hg and complete anuria for 48 hours. When venesection, pantopon, digitalis, etc., produced no effect, diathermy was applied intensively for 2 hours to both kidneys, with the result that urine was voided immediately. Under further treatment of the same kind, improvement was rapid; all cerebral symptoms had disappeared by the end of the second day; diuresis amounted to 1600 c.c. on the 4th day, and blood pressure was 120 m.m. Hg on the 5th. The urine was free of albumin on the 12th day. In cases of eclampsia it is advisable to combine diathermy of the kidneys with that of the head. Without venesection or lumbar puncture, severe cases have yielded promptly to this treatment, which is especially recommended to gynecologists for use in puerperal eclampsia. Results in chronic nephritis are not so encouraging. After treating a number of cases for months at a time, the author could report no unequivocal successes, although headaches, rigidity of the neck, and similar cerebral symptoms showed some improvement. Favorable subjective effects lasted only a day or two, and diathermy had to be repeated every second day. In subchronic cases and in contracted kidney it is difficult to evaluate the effects of treatment. The method is useful in prognosis, since in unfavorable cases diuresis remains unaffected even with normal rest nitrogen, under repeated control, whereas in more favorable cases improvement is observed within a few hours. It is difficult to specify a standard dosage. In acute glomerulonephritis as a rule 2 treatments a day of 3 to 4 amperes each, and lasting 2 hours, are given. Sometimes an interval of 1, 2, or 3 days is desirable between treatments, inasmuch as diuresis is in some cases better on the day following treatment than on the day the diathermy is applied.

Uses of Diathermy in Medicine and Surgery.—After reviewing the growth of diathermy, E. P. Cumberbatch states that this agency is used to relieve pain and spasm, to raise temperature which is pathologically subnormal, to lower blood pressure which is unduly high, and to aid in the resolution of inflammation. It also aids the tissues in freeing themselves from local and general infection. Surgical diathermy, known as desiccation or fulguration, is of high value in the treatment of morbid tissue which does not extend deeply below the surface. In gynecology diathermy has achieved striking success. By the C. A. Robinson method the urethra and cervix can be safely and painlessly heated to a temperature of 114°F. This high degree of heat aids them in freeing themselves from infection. By this method success has been obtained in 90 per cent of gonococcal cases, and in 80 per cent of non-gonococcal cases. By reason of their deeper situation it is not possible to heat the tubes and ovaries to the same high temperature as the urethra and cervix, but the relatively minor degree of pyrexia that can be produced in the tubes is often successful in bringing salpingitis to an end. General pelvic diathermy is successful in dysmenorrhea, and it seems to influence the endocrine functions of the ovaries. In diseases peculiar to men the most favorable results are obtained in gonorrheal infection, including gonorrheal prostatitis and vesiculitis. In anterior urethritis diathermy is disappointing. In a few cases of senile prostatic enlargement not of long standing, Cumberbatch has been successful in removing the symptoms of obstruction by the use of diathermy. In the treatment of gonorrheal arthritis, it is imperative that the prostate and vesicles (in men) and the cervix uteri (in women) should be subjected to diathermy. This form of treatment invariably brings the arthritis to an end. In the treatment of hyperpiesia and angina pectoris diathermy has proved useful. Its value in pneumonia has been demonstrated by Eaton Stewart. Cumberbatch has found it valuable in the treatment of mucous colitis. In certain skin diseases, notably mulberry nevus, capillary nevus, telangiectasis, pedunculated warts, and pigmented areas, diathermy has been effective. In lupus vulgaris and for epithelioma of the skin diathermic coagulation and fulguration are of value. Glaucoma and gonococcal iritis have been alleviated by diathermy. Xanthelasma palpebrarum can be successfully treated by fulguration. In malignant disease surgical diathermy has scored some meritorious results.—*The Lancet*, February 7, 1931, ccxx, 5606.

Hypoglycemic Reaction from Adrenalin in Cirrhosis of the Liver.—Arturo Tarsitano re-

ports a peculiar behavior of the blood sugar curve in 5 patients suffering with cirrhosis of the liver, 4 being of Laënnec and 1 of Banti type of the disease. All the patients were injected fasting with 1 mg. adrenalin in the morning, and remained in bed during the 3 hour test. The injections were made into the deltoid or pectoral region to assure complete absorption in edematous patients, and the blood sugar was tested every half hour for 3 hours after injection. Instead of an increase in the fasting blood sugar a reduction was observed, a paradoxical adrenalin glycemia. The graphs obtained showed 3 different modes of behavior: (1) a curve that was clearly hypoglycemic, with a return to the initial values in the blood in the 3 hours following injection of adrenalin; (2) a curve just as clearly hypoglycemic, which had not returned to the initial values in 3 hours, and (3) a curve descending irregularly, with the blood sugar values after 3 hours less than the initial fasting blood sugar. It is not claimed that a hypoglycemic reaction is a constant finding in hepatic cirrhosis, for in a sixth patient it did not occur. The cases are reported for their biologic interest. The curves may have been due to a combination of two factors: on the one hand, an absence of glycogenolysis on the part of the liver under the stimulation of the adrenalin, through exhaustion of its glycogenetic reserves; and, on the other hand, a condition of hyperinsulinemia brought about by the exciting action of the adrenalin upon insulinogenesis, by way of the humoral system. It is impossible to exclude the possibility of an influence exerted by sclerosis of the thyroid that nearly always accompanies cirrhosis of the liver, and which would thus furnish a hypothyroid soil having little power of reacting to sympathetic stimuli. While neurovegetative factors may have had an influence, there seems no doubt, when the liver is compromised by a grave lesion, that the hepatic factor is the predominating one.—*Riforma medica,* December 8, 1930.

Cinchophen and Acute Yellow Atrophy of the Liver.—After referring to cases reported in the literature in which cinchophen caused acute yellow atrophy of the liver, William G. Walker describes two cases coming under his observation. The first patient, a laborer 43 years of age, was seen by the author on October 10, 1929, because of jaundice and coma which had lasted for two days. It was learned that the man had taken about twenty-four 4-grain tablets of cinchophen during the third week of the preceding August. Death ensued in less than twenty-four hours. The second patient was admitted to the hospital on January 28, 1930, because of nausea and progressive jaundice. During July, 1929, she had taken one hundred 7½-grain cinchophen tablets for arthritis. The drug relieved the joint pains and caused no distress. Three weeks before entering the hospital she again took cinchophen, and immediately heartburn, nausea, and anorexia ensued. She, nevertheless, continued using the drug until she had taken about thirty 7½-grain tablets. In the course of a few days she became deeply stuporous. Sugar appeared in the urine, but was controlled by insulin. In both cases leucine crystals were found in the urine. In both the administration of physiological saline and glucose solution was without effect, and autopsy showed the typical picture of acute yellow atrophy of the liver. Rabinowitz has, recently, again called attention to the fact that many analgesic remedies contain cinchophen or one of its derivatives, and unless one knows the constituents he may unwittingly prescribe the drug. He further states that toxic effects cannot be prevented by small or intermittent dosage, nor by the simultaneous use of sodium bicarbonate or of large amounts of fluid.—*New England Journal of Medicine,* February 5, 1931, cciv, 6.

The Early Diagnosis of Extrauterine Pregnancy.—Samuel R. Meaker calls attention to the fact that, while the classical picture of early ectopic gestation is well defined, extrauterine pregnancy may present very variable symptoms and signs, often atypical, and sometimes closely simulating other conditions. It may be confused with miscarriage in early uterine pregnancy. In both conditions the history includes a missed period followed by spotting or staining; typical disturbances in breasts, stomach, and bladder; and a certain amount of pain. In both, the examination may reveal a large, soft uterus and some degree of pelvic tenderness. Any type of pelvic inflammatory disease may give rise to irregular staining, gastric and vesical symptoms, lower abdominal pain, enlargement and softening of the uterus, local tenderness, and to masses at the side of the uterus or in the posterior culde-sac. The coexistence of pregnancy and inflammatory disease occasionally produces a clinical picture almost identical with that of early ectopic pregnancy. Torsion of the appendages may suggest ectopic pregnancy. On the other hand extrauterine pregnancy may present an atypical picture. In about 35 per cent of these cases there is no history of a missed period. Mammary, gastric, and vesical symptoms may be absent, or only such as the patient customarily notes before menstruation. Frequently the gravid tube cannot be recognized by palpation. Special diagnostic aids, such as the past history, the temperature, the white blood count, the sedimentation test, the

Aschheim-Zondek test for pregnancy, Cullen's sign, ether examination, and posterior colpotomy, are of limited value. In the suspected case the closest attention should be given to the character of the pain. In the early case pain is irregular in occurrence, severe in degree, and sharp in character, and often radiates to the shoulder, the back, or the thighs. Many patients complain that it hurts them to sit down. The sharp, severe attacks are frequently accompanied by weakness or faintness. If obvious acute inflammation is not present, then any great pelvic tenderness, aggravated by movement of the uterus, is highly suggestive of extrauterine pregnancy. In the early case a short period of observation often serves to clarify the diagnosis.—*New England Journal of Medicine*, February 12, 1931, cciv, 7.

Successful Treatment of Tabes Dorsalis with Endolumbar Salvarsan. — Theodor Brunner calls attention to the results of his 8 years' treatment of tabes dorsalis by means of endolumbar injections of salvarsan. A questionnaire sent to 11 patients who had received the treatment elicited the information that in 6 of the 11 (55 per cent) full functional capacity had been restored over a period of 7, 5, 4½, 2, 2, and 1 years, respectively. Two patients (18 per cent) had functional capacity amounting to 50 per cent, and the other 3 (27 per cent) reported improvement. This means that functional capacity had returned in the first two classes after the second or third treatment, often in an astonishing manner. Step by step with the improvement there was a diminution or total disappearance of the pains. Bladder disturbances ceased, and the general condition grew better, especially the general appearance and the body weight. Serological examination showed that in 4 cases the spinal fluid was completely normal, in 6 cases nearly normal, and in one case, normal before treatment, unchanged. The restoration of the spinal fluid extended to every detail of its qualities as a rule, and took place with extraordinary rapidity. In most cases serological improvement and clinical improvement ran parallel; in a few, however, this agreement was not always present, and the incongruity was not confined to the Wassermann reaction. The reasons for this were not entirely clear. Occasionally very good clinical findings were observed where there was still a pathological cerebrospinal fluid. In both fresh and more advanced cases of tabes, endolumbar treatment should be the first resorted to. At the same time a series of intravenous salvarsan treatments are arranged to follow, alternating with bismuth preparations and also iodine therapy by mouth.—*Schweizerische medizinische Wochenschrift*, January 17, 1931.

Cataract Operation in Extreme Old Age.—R. H. Elliot, writing in the *British Medical Journal*, January 24, 1931, i, 3655, states that he has on four occasions operated on patients 90 years of age or older, two of them being 95 and 96 years of age, respectively. He also includes the report of the case of a man, aged 96 years, operated upon by Kirkpatrick. In addition, Elliot has operated on a very large number of patients between the ages of 80 and 90. It is worth noting that in all five patients over 90 the operation was successful. In none of them was the shock of the operation severe, and in no instance does it seem to have shortened life. In seeking the reason why these patients of advanced years stand operation so well, Elliot thinks the answer lies in the extraordinary vitality that has enabled them to live twenty years and longer beyond what is usually accepted as the allotted span of life. Incidents in connection with the various activities of these patients illustrate the vitality which radiates through these exceptional specimens of the human race. Their protoplasm seems to be of a more active and resistant nature than that of most of their fellows, and this probably makes them good subjects for operation. It is of significance that such people usually have warm hands and feet —an indication of an active thermotaxic center and of excellent circulation.

The Relations between Body and Psyche.—There is a close dependence, according to Ad. Oswald, of the psychic experience upon what befalls the body, and likewise of the bodily activity upon what befalls the psyche. Both parts, psyche and soma, are closely interwoven; they fit into one another continuously, and mutually control each other. When we take into consideration the great number of observed facts which substantiate this inner companionship, this intimate interweaving, and its extension to all bodily functions, the impression is forced upon us that all somatic processes go hand in hand with a psychic experience (though we must admit this is for the most part buried in the unconscious deeps of our being), and that, on the other hand, all the contents of our psyche find a somatic resonance. From this it follows that the two components, body and psyche, are not two realities existing side by side, but are parts of one unitary whole, the psychophysical condition which is life itself. Under this concept the life process appears as a phenomenon which plays its rôle partly in the material and partly in the immaterial ("irrational"). At bottom it is one and the same process, which we see only from a dual point of view, as we do vibrations and light, as "two emanations of one living en-

tity." We can never grasp the homogeneity of the two with our senses, because the power to perceive and to comprehend it is lacking. The ancients saw an inseparable unity in body and mind, which later teachings turned into a dualism. Even though we succeed in getting a glimpse of the psyche as power, the next step, the recognition of the essence of the psychic subjectivity, the nature of the consciousness, remains for us an insoluble riddle, and must so remain as long as our somatic-psychic organization stays at its present stage of evolution. That a further phylogenetic evolution of our being may bring improvements to which this step is possible, is not to be denied *a priori*. An attack of illness depends not only on the type, form, volume, and cause of the disease of the organ, but also upon the psychic nature of the patient. The psyche assists the individual reactiviy to the disease, and in great degree by its manifold attitudes causes one and the same disease to assume a wide variety of forms.—*Schweizerische medizinische Wochenschrift,* January 10, 1931.

Orthopnea.—It was observed by H. Eppinger, D. Lazlo, and A. Schürmeyer that many cardiac patients are unable to remain lying in a horizontal position in bed, owing to difficulty in breathing. After assuming this position, they are obliged in a few moments and with considerable abruptness to elevate the upper portion of the body. This seems to point to some sudden factor making its appearance without warning. It is a well-known fact that many persons on lying down become flushed in the face. It is also well known that the brain pulse after a trepanation almost disappears if the patient is placed in a recumbent position. In the belief that a study of the circulation in the carotid artery and jugular vein would throw some light on the subject of this sudden orthopnea, the authors carried out experiments in a dog placed on a table that could be raised and lowered at will. They found that when the head is lowered the brain circulation is poorer than in its normal upright position. The pulse tracings showed that while the flow of blood through the common carotid decreased, that through the external jugular vein was considerably increased. This could only be explained by the greater part of the blood flowing through the external carotid and the much smaller part through the brain. Again the tracings showed that at the moment the head was lowered the brain circulation decreased while that in the femoral vein increased. This leads to the conclusion that in many uncompensated cardiac cases the venous pressure is essentially higher than in normal persons, and that in those with heart failure the horizontal position causes this venous pressure to rise to a far higher degree than in those who are healthy. We can therefore conceive that under the influence of increased venous pressure the brain, already poorly supplied with blood, is placed at a still greater disadvantage, which may be a cause of orthopnea, explainable by poor circulation through the respiratory center. Since even under normal conditions the brain is poorly supplied with blood when the head is lowered, the venous stasis in the region of the superior vena cava, which increases on lying in a horizontal position, would be likely to increase this circulatory involvement still further.—*Klinische Wochenschrift,* January 3, 1931.

Observations on the Etiology and Treatment of Paroxysmal Ventricular Tachycardia.—Edward H. Schwab reports three cases of ventricular tachycardia, two of the usual type and one of the alternating bidirectional variety. In one case the paroxysms were associated with persistent atrioventricular rhythm, a combination not previously reported in the literature. All three patients were treated with quinidine with uniform success in controlling the arrhythmia. In all cases reported in the literature in which the drug has been used, similar success has been attained. The drug is apparently just as specific in controlling the alternating bidirectional variety as in the usual type, although no definite conclusion can be drawn from one case. The amount of quinidine necessary to produce therapeutic results varies greatly. When the patient's condition is critical, it is perhaps best to administer the drug intravenously. In the first case the patient who had been taking quinidine was given digitalis, and instructed to return for observation. He failed to return and continued taking the digitalis, which was undoubtedly a factor in precipitating the ventricular tachycardia. It is quite generally agreed that digitalis plays an important part in the etiology of this condition. In a review of all the cases of both types, it has been found that this drug has been administered prior to the onset of the arrhythmia in approximately 50 per cent of the cases, and in the majority of these it was taken in excessive amounts. The association of digitalis and ventricular tachycardia is much closer in the alternating bidirectional variety than in the unidirectional form; all the reported cases in which the records are clear, except two, had received the drug in toxic amounts. Because of the close association between coronary occlusion, digitalis, and ventricular tachycardia, digitalis should be administered with extreme caution to patients who give a history of a recent cardiac infarction.—*American Heart Journal,* February, 1931, vi, 3.

LEGAL

CHARITABLE HOSPITAL—LIABILITY FOR NEGLIGENCE OF ITS PHYSICIANS AND NURSES

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

With the exception of those hospitals run as a business enterprise for profit and commonly known as sanitariums, the vast majority of the hospitals in this State are incorporated and operated as charitable, not-for-profit institutions. The question has very often arisen as to whether such an institution is answerable to a patient in money damages for the claimed negligence of one of its physicians, nurses, orderlies, etc.

The law is now settled beyond dispute in this jurisdiction that a charitable, not-for-profit hospital is not responsible for the negligence of its physicians, nurses, orderlies, etc., so far as a patient of the hospital is concerned, unless the hospital has failed to use due care in the selection of the particular individual causing the injury. The rule applies with equal force whether the patient in the hospital is a ward patient or a private patient. It is also well established that the burden of proof that the hospital has failed to use due care in the selection of a particular physician, nurse, orderly, etc., rests upon the plaintiff, and it is also well settled that a single act of negligence on the part of anyone connected with such an institution in his relations with the patients of the hospital does in any wise establish or tend to establish the general incompetency of such individual so as to render the hospital liable.

The distinctive features of a charitable, not-for-profit institution are very well stated in one of our great encyclopedias of law (Corpus Juris) as follows:

"Their (charitable hospitals') principal and distinctive features are that they have no capital stock and no provision for making dividends or profits, but derive their funds mainly from public and private charity and hold them in trust for the object of the institutions. In other words, the test of whether an enterprise is charitable is whether it exists to carry out a purpose recognized in law as charitable, or whether it is maintained for gain, profit or private advantage."

Of course the principle here enunciated does not apply to a private sanitarium or to any hospital run as a business enterprise for profit. Institutions of this character are liable for the negligent act of their employees upon the doctrine of respondeat superior, in exactly the same manner as any corporation is liable under the law for the negligence of its agents, servants or employees acting within the scope of their authority.

Through a number of well considered cases in this State, it has been definitely established that physicians, nurses, orderlies, etc., are not in law considered to be the agents, servants or employees of the hospital; the law treats them as independent contractors, each liable to the patient for any wrong that the patient may suffer at his hands from negligence, but involving the hospital in no liability.

Exactly what a charitable hospital undertakes to do with respect to a patient is very well stated in one of the leading cases as follows:

"The business of a charitable corporation maintaining a hospital is to furnish to those who are ill facilities for skillful treatment and care. It does not contract to heal or attempt to heal a patient through the agency of others. At the most it undertakes to permit the use of its facilities and to supply others who will heal or attempt to heal on their own responsibility."

The reason for the rule here discussed, as well as its application to the acts of physicians and nurses so far as the hospital is concerned, is very clearly stated in a leading case on this point as follows:

"Certain principles of law governing the rights and duties of hospitals when maintained as charitable institutions have, after much discussion, become no longer doubtful. It is the settled rule that such a hospital is not liable for the negligence of its physicians and nurses in the treatment of patients. . . . The hospital remains exempt though the patient makes some payment to help defray the cost of board (citing cases). Such a payment is regarded as a contribution to the income of the hospital to be devoted, like its other funds, to the maintenance of the charity. The second ground of the exemption is the relation subsisting between a hospital and the physicians who serve it. It is said that this relation is not one of master and servant, but that the physician occupies the position, so to speak, of an independent contractor, following a separate calling, liable, of course, for his own wrongs to the patient whom he undertakes to serve, but involving the hospital in no liability if due care has been taken in his selection. On one or the other, and often on both of these

pital has been held immune from liability to patients for the malpractice of its physicians. . . .

"It is true, I think, of nurses as of physicians, that in treating a patient they are not acting as the servants of the hospital. The superintendent is a servant of the hospital; the assistant superintendents, the orderlies, and the other members of the administrative staff are servants of the hospital. But nurses are employed to carry out the orders of the physicians, to whose authority they are subject. The hospital undertakes to procure for the patient the services of a nurse. It does not undertake through the agency of nurses to render those services itself. The reported cases make no distinction in that respect between the position of a nurse and that of a physician (citing cases); and none is justified in principle."

At this point it should be noted that the rule exempting charitable hospitals for the negligence of those connected with the hospital does not apply in this jurisdiction unless the injured party is a patient in the hospital. A review of one of the leading cases is sufficient to demonstrate the distinction thus created.

An action was begun against a charitable institution by a plaintiff who was injured while engaged in making repairs on a boiler in defendant's premises. At Trial Term the complaint was dismissed on the ground that the defendant was a charitable institution, and the Appellate Division unanimously affirmed. The plaintiff then brought the case to the Court of Appeals, where it was held that under the facts disclosed in this case the defendant was not immune from liability simply because it was a charitable institution.

It is interesting to note that in other jurisdictions the doctrine of exemption has been extended beyond the rules laid down in this State. For example, in a recent case in Missouri an action was brought by the plaintiff who was employed as an elevator operator in a building owned and used by a charitable institution. The upper floors of the building, however, were almost entirely rented to tenants engaged in various business pursuits. The plaintiff was injured while about to descend from an upper floor, after having discharged a passenger. In the action brought against the charitable institution based on its alleged negligence in failing to provide certain safety devices, the defense was that as a charitable organization it was exempt from liability for negligent injury, and that its status as such organization was not affected by its leasing of rooms. The court held for the defendant and ruled that the income from the rented rooms was devoted to the general charitable purposes of the defendant and thus was impressed with a trust which could not be diverted to pay damages.

It must be borne in mind that the exemption accorded to a charitable, not-for-profit institution is not a defense in an action brought by the patient against any individuals connected with the hospital for their alleged negligence. Although the hospital is exempt under the circumstances and for the reasons here stated, the individuals connected with the hospital remain liable for their individual acts.

ALLEGED NEGLIGENT OPERATION DURING PREGNANCY

The plaintiff in this case consulted the defendant, a physician and surgeon, giving a history of having given birth to a child about five months previous, and complaining that subsequent to said birth her menstruation had been irregular and said menstruation was followed by a thick, creamy foul-smelling discharge. She also complained of pain.

The doctor made a diagnosis of retroversion, prolapse of the uterus, endocervicitis and a rectocele.

The doctor suspected that she feared another child-birth and desired him to perform an operation upon her. He did not at any time suggest or agree to perform a curettage.

The woman was hospitalized and the doctor performed an operation for suspension of the uterus, cauterizing the cervix and performing what is known as an Emmett perineorrhaphy. Her recovery being uneventful she was discharged in about four weeks.

Shortly thereafter, the patient instituted a suit against the doctor, in which it was alleged that the defendant doctor had advised the plaintiff that it was necessary for him to perform an operation upon her uterus to straighten it, and also to perform a curettage, and that defendant was negligent in that (first) he failed to perform the curettage which he had advised the plaintiff he would perform, and (secondly) that he failed to recognize that the plaintiff was pregnant at the time.

Incidentally, it should be noted, that a few months after the institution of the suit the plaintiff was delivered of a normal child, and her physical condition was very good.

When the case was brought on for trial the plaintiff's lawyer attempted to negotiate some sort of a settlement, but the attorney for the defendant, confident that the doctor had in no way been guilty of malpractice, refused to settle the case at any figure and insisted that the matter be tried in court. The plaintiff's attorney then consented that the case be dismissed upon the merits, thus terminating the matter.

CLAIMED NEGLIGENT TREATMENT OF FRACTURE OF HUMERUS

In this case a patient was referred to the defendant doctor for surgical treatment of an injury to her right arm which had been sustained from a blow received while riding in an automobile with her arm out of the window Upon examination the doctor found that she had a spiral fracture of the lower third of the right humerus He immediately took her to the operating room of the hospital, put her under gas and oxygen anesthesia and attempted to reduce the fracture. As the arm was badly swollen, he found reduction was impossible at that time and, therefore, put the arm in a splint and had an X-ray picture taken which showed the fracture not reduced. He then put the arm in suspension and skin traction until the swelling subsided. He adjusted the traction from time to time for about two weeks, when he had another X-ray picture taken which showed the position of the bones to be satisfactory. The doctor then applied plaster splints moulding the fragments. A picture taken through the splints showed an almost complete reduction with almost perfect alignment.

The patient then left the hospital and visited the doctor at his office on several occasions, at which times the splints were removed and reapplied as appeared necessary to the doctor. After several weeks the doctor found the arm solid with good callus, and the patient was able to move her arm freely and could straighten it to about thirty percent of full extension. She complained, however, of pain in the arm at the point of fracture. The doctor advised her to exercise the arm and, if the pain continued, to return to him and he would have further X-rays taken.

However, the patient never returned to the defendant but subsequently went to another physician about two months later who discovered that the fracture was ununited. This physician advised her to return for treatment to the first doctor but she refused, and at her request the second physician performed an open operation and by means of bone graft succeeded in causing her to have a good end result.

Suit was instituted against the first doctor by the patient who claimed that he had negligently treated her and failed to properly reduce her fracture, and that solely through his negligence the plaintiff was compelled to undergo a surgical operation to remedy her condition. The action was brought on for trial before a judge and jury, and a verdict was rendered in favor of the defendant doctor.

NEEDLEBREAK DURING NOVOCAINE INJECTIONS

The defendant in this case, a specialist in neurology, was called to the home of a woman whom he found in bed suffering from what appeared to be sciatica of the left leg. He decided to give her injections of novocaine saline solution in the epidural space. After sterilizing the needle and the field, he made two injections and was attempting the third when, while forcing the fluid into the cavity or space, the patient suddenly jerked her body upwards. The doctor heard the needle crack. He took it out and found about one inch missing.

The doctor probed a bit for the needle and, as he could not find it, decided that it had dropped down into the space. He arranged for the patient to call at his office a few days later, at which time she was much improved in her sciatica. The doctor took an X-ray picture of the region which showed the location of the needle. He then made an incision over the spot, probed for the needle but was unable to locate it. As he did not think it wise to attempt to chisel the bone in order to lift the needle out, he sent the patient home and later after the wound had healed he made a second attempt to remove the needle. At this time another incision 1½ inches long was made, but the doctor was again unsuccessful. For the reason that the needle was giving the woman little trouble, the doctor then concluded that it would be best to allow the foreign body to remain in the leg. When the doctor last saw the woman, the wounds at the points of incision were completely healed and the patient seemed to suffer no discomfort of any kind.

Actions were started by the patient and her husband in the Supreme Court by the service of summonses, the patient apparently intending to charge the doctor with malpractice in permitting the needle to enter and remain in the woman's body. Complaints were not served with the summonses, however, and at the request of the attorney for the plaintiffs the defendant's counsel agreed that the time for the plaintiffs to serve their complaints should be extended for a period of several weeks. The plaintiffs' attorney failed to serve either of the complaints, and after nearly three years had elapsed motions were made in behalf of the defendant to dismiss the actions by reason of the delay of the plaintiffs' attorney. Upon the hearing of the motions, the court granted the same and dismissed the actions.

NEWS NOTES

COMMITTEE ON PUBLIC RELATIONS

A meeting of the Committee on Public Relations was held in the Albany office on Friday, March 13, 1931. There were present Drs. Sadlier, Fisher, Johnson, Hambrook and Lawrence. Drs. Mitchell and Ross were excused because of illness.

The sub-committee composed of Drs. Johnson and Hambrook, having arranged an appointment with Commissioner Parran for 9.30 A. M., invited the other members of the committee to accompany them. They discussed with the Commissioner the question of how hospitals should be selected for endorsement as county general state-aided institutions. Two instances were available where institutions not financially successful under present management, had applied or were about to apply to their local boards of supervisors to be taken over and reorganized as county state-aided general hospitals.

During the conference the law under which the Commissioner must act was carefully considered and it was noted that under the general municipal law county boards of supervisors may, by vote of the people, take over or establish and operate general hospitals at the expense of the county. If State aid is desired, the board of supervisors must secure control of the hospital in like manner by submitting the proposition to the voters of the county or secure legislative authority for acquiring the hospital by resolution.

The next step in the procedure is to make application to the Commissioner of Health for State aid, giving reasons and a statement of budget. If the Commissioner is persuaded that there is a need for such general public health hospital and is satisfied with the budget, and statement from the board of supervisors is satisfactory, he shall agree to the request of the Board and include in his budget for the next year an amount of money equal to one-half that appropriated by the supervisors for the conduct of that hospital during that time.

The Commissioner is bound in no way to make this appropriation except from year to year, nor is he bound to accept conditions or a statement of budget from hospitals except by investigation he satisfy himself they are reasonable. He requested that the Committee on Public Relations be agreeable to assisting him, if he felt he needed assistance, in determining requests of this character that may come to him in the future.

It was reported that public welfare workers feel that physicians coming out of medical schools at the present time should have a wider acquaintance with the new public welfare law before they start to practice. The justice of this criticism was admitted by the committee and at Dr. Fisher's suggestion, seconded by Dr. Hambrook, the chairman was authorized to communicate with the deans of the medical schools, asking that adequate provision be made for acquainting medical students with the provisions of the public welfare law.

It was also suggested that there is still considerable difficulty in certain counties with regard to the administration of the law and a motion was made and passed that Dr. Ross be invited to describe the procedure followed in Suffolk County in arriving at an understanding between the County Society and the commissioner of public welfare as to the manner in which the work should be administered in that county—this write-up to be published later as a pamphlet from this committee.

The date for the next meeting was tentatively set as Thursday, April 16th, in Albany, and the Executive Officer was asked to invite the proper persons to represent federated labor.

A series of five-minute health talks on the legislative program proposed by the New York State Health Commission is being broadcast by radio from station WGY, under the direction of Dr. Thomas Parran, State Commissioner of Health. This first one of the series was given on March 4, by Dr. W. H. Ross, President of the Medical Society of the State of New York, who developed the idea that the Commission considered the distribution of medical service by municipalities, rather than its production by physicians.

Another talk of the series was that given by Dr. James E. Sadlier, Chairman of the Committee on Public Relations, who said in part:

"The three great groups that are working to prevent disease throughout this state are, (1) The State Department of Health, (2) The Medical Profession of the State, and (3) Lay Organizations working in the health field. These three groups are cooperating, coordinating and harmoniously working together for the betterment of public health. Perhaps the most important change that is recommended by the State Health Commission is to make the county the unit of local health administration.

LEGISLATION

BULLETIN NO. 8—MARCH 11, 1931

Since our last bulletin the following bills have been introduced:

Senate Int. No. 1,256-Hofstadter (Assembly Int. No. 1,630-Austin), to amend the Mental Hygiene Law by providing for the removal or commitment of insane or apparently insane persons for care, treatment or observation for limited period, to psychopathic wards. Referred to the General Laws Committee.

Senate Int. No. 1,315-Buckley (Assembly Int. No. 1,500-Sullivan), adds new article 11-a and repeals section 181-a, of the General Business Law, relative to nurses' registries. Referred to the Committee on General Laws.

Senate Int. No. 1,319-Wicks (Assembly Int. No. 1,887-Gimbrone), adds new section 20-a, Public Health Law, requiring health officers in cities of more than 50,000 to devote entire time to duties of office and not engage in the practice of medicine. Referred to the Health Committee.

Senate Int. No. 1,345-Brereton (Assembly Int. No. 1,865-Porter), amends section 21-c, Public Health Law, by providing appointment by health officers of public health nurses must be approved by district health board. Referred to the Health Committee.

Senate Int. No. 1,346-Brereton (Assembly Int. No. 1,864-Porter), amends section 20, Public Health Law, to permit health board of a consolidated district to include in estimate of expenses sum for employing a nurse in connection with business of a lying-in asylum and for public health work. Referred to the Health Committee.

Assembly Int. No. 1,687-Kahan, amends the Education Law by providing medical inspection of school children shall include services of physicians and dentists. Referred to the Education Committee.

Assembly Int. No. 1,723-Doyle, adds new section to the General Business Law, prohibiting broadcasting of any speech or remarks relating to medicine or using medical terms or to diagnose any disease or to recommend cure, unless by a duly licensed physician. Referred to General Laws Committee.

Assembly Int. No. 1,724-McKay, amends the Education Law by prohibiting the practicing of optometry from house to house or on the streets or highways. Referred to the Education Committee.

Assembly Int. No. 1,855-Cornaire, amends the Workmen's Compensation Law by listing as occupational diseases fibrosis of respiratory tract due to exposure to silica or rock dust. Referred to the Labor Committee.

The anti-vaccination bill has been introduced in the Assembly—Int. No. 1,702-Wemple.

Action on Bills

The Hickey-Piper optometry bill—Senate Int. No. 441, Assembly Int. No. 727—has passed the Senate and advanced to third reading in the Assembly.

The Cilano-Esmond qualified psychiatrists bill—Senate Int. No. 344, Assembly Int. No. 442—was killed in the Assembly.

Hearings

March 18—2:00 P. M.—Before Joint Committees on Finance and Ways and Means—the Wicks-Hutchinson health bill, Senate Int. No. 993 (Print No. 1,111); Assembly Int. No. 1,362 (Print No. 1,491).

Please note the date of this hearing and send such advice as you may have prior to that time; also communicate with the committees before whom arguments on the bill will be heard.

PLEASE NOTE THE FOLLOWING: The osteopathic bill has been amended and reported out of the Education Committee in the Assembly. Last week we were given the opportunity through our Executive Officer, of discussing this bill before the Assembly Committee on Education and we stated that we were unalterably opposed to granting osteopaths the privileges accorded by the bill, on the ground that they had had no training whatever in the use of drugs. This morning we are advised that the following restrictions upon the use of drugs have been placed in the bill: That osteopaths be permitted to use only antiseptics, anesthetics, narcotics, vaccines, serums and antitoxins. We must put up, immediately, vigorous opposition to this bill if we mean to prevent its passage by the Assembly as we did last year. *Communicate immediately* with your Assemblymen and have all of your friends do the same. Last year the Assembly was flooded with letters from friends of the osteopaths. It is no exaggeration whatever to say that the leader of the Assembly received hundreds of letters not only from citizens of his district, but from persons all over the state. We cannot urge too strongly that you do your utmost to assist us in developing opposition in the Assembly to this bill.

SPECIAL BULLETIN—MARCH 17, 1931

The amended osteopathic bill is enclosed—Senate Print No. 1,658. It is before both Houses. In the Senate it is on General Orders and can be called out for a vote at any time. In the Assembly it was advanced last night to third reading and may come on the calendar for final reading on Thursday; or probably. Because it is a highly controversial matter, it may be post-

poned until Monday evening when action may possibly be taken.

Certain features presenting themselves this year must be thoroughly appreciated:

1. Ex-Deputy Commissioner Augustus Downing of the Department of Education is the author of the bill;

2. The impression prevails very generally that the Department of Education is not opposed to the bill. Actually, we know this impression is false, but the Department has made little or no effort to repudiate it;

3. In the Senate the bill is sponsored by Mr. Fearon, whom you all know very well, and in the Assembly by Mr. Tellier, who has been its sponsor for several years;

4. Only two or three legislators have told us that they have had letters from home opposing the bill, while almost every man has shown us quantities of letters from osteopaths and their friends in favor of the bill.

Unless each one receiving this bulletin immediately communicates with his legislators and persuades as many other persons as he possibly can find to do the same, the osteopathic bill will be passed by both Houses within another week. It remains with you as to whether this shall happen.

SPECIAL BULLETIN—MARCH 19, 1931

Assembly Int. No. 2004-Robinson, would give hospitals a lien upon the automobile patients that have been so expensive in recent years. You will observe that this carries no provisions for nurses and doctors. We think it wise to urge the passage of this bill without insisting upon the doctor and nurse being included at this time, profiting by our experience in previous years when we insisted upon such an amendment and lost the whole bill. If this bill can be enacted, it will be easy in another year to have it amended so as to make special provision for doctors and nurses.

Assembly Int. No. 2037-Hartshorn, has a bearing upon a certain type of activity in the vicinity of large industries, particularly in New York City. We are told that certain physicians are conducting their offices in the manner of dispensaries, but are not under the Dispensary Law because they mark their offices as clinics or with some other particular designation. A survey made by the Department of Labor a year ago pointed out that many of these places are not above criticism and this bill aims to rectify that condition and bring the physicians under proper supervision.

BULLETIN NO. 9—MARCH 20, 1931

Since our last bulletin the following bills have been introduced:

Senate Int. No. 1469-Wicks (Assembly Int. No. 1955-Austin), amends the Public Health Law by giving the county health commissioner equal authority with a local board to investigate and abate public nuisances affecting health. Referred to the Health Committee.

Senate Int. No. 1491-Gates (Assembly Int. No. 1981-C. P. Miller), amends the Workmen's Compensation Law by providing board may within three years instead of one, from date of accident, reclassify a disability. Referred to the Labor Committee.

Senate Int. No. 1511-Webb (Assembly Int. No. 2017-Rice), amends the Education Law relative to physically handicapped children, by defining as a physically handicapped child, "A person under 21 years of age who by reason of a physi- ect or infirmity, whether congenital or ac- by accident, injury or disease, is or may ected to be totally or partially incapacitated lucation or for remunerative occupation." ed to the Education Committee.

sic third
nicip or f
cians. cau
Anothe ay Int. No. 1596-Schackno (Assembly Int. Robinson), amends the Lien Law to s a lien on rights of actions, suits, laims or demands of a person admitted to a hospital on account of personal injuries. Referred to the Judiciary Committee.

It will be recalled that a lien bill was before the legislature two years ago and met with such powerful opposition that it did not get out of committee. We urged that doctors and nurses be included in that bill. It seemed to us afterwards that probably it would have been wiser to have favored the bill as it was written and after it had been enacted a year or two, have it amended so as to include doctors and nurses. We shall try such policy this year.

Senate Int. No. 1617-Byrne, amends the State Charities Law and the Penal Law for the licensing of hospitals. This is the hospital bill that we favored last year. It has been introduced this year simply in order that it may be printed and studied. No effort will be made to advance it. Referred to the Judiciary Committee.

Senate Int. No. 1625-Gates (Assembly Int. No. 2132-C. P. Miller), amends the Workmen's Compensation Law by providing time limit for contracting disease under this section shall not bar compensation in case of employee who contracted disease in employment with same employer by whom he was employed at time of disablements. Referred to Labor Committee.

Assembly Int. No. 2127-Dickey, adds a new

section to the Public Health Law, directing State Health Commissioner to establish a bureau for enforcing provisions with respect to habit-forming drugs. Referred to the Health Committee.

Senate Int. No. 915-Fearon; Assembly Int. No. 1277-Tellier—osteopathic bill. See special bulletin of March 17th. (Page 425.)

Senate Int. No. 263-Hastings, medicinal liquor bill, has passed the Senate.

Assembly Int. No. 491-Story, health commissioner appointed by mayor, has been amended to make it essential that the appointee be a member of his county medical society.

Senate Int. No. 441-Hickey, optometry bill—has passed both houses and gone to the Governor.

Assembly Int. No. 2037-Hartshorn, amending the charities law with regard to dispensaries and clinics, has been reported out of committee.

Assembly Int. No. 636-Porter, chiropractic bill, has been reported out of committee in the Assembly.

* * * * *

The following Assembly bills have been reported killed in committee:

Int. No. 52-Horn, amending the Workmen's Compensation Law.
Int. No. 143-Vaughan, anti-vivisection bill.
Int. No. 221-Cuvillier, motor vehicle compensation law.
Int. No. 236-Esquirol, occupational diseases.
Int. No. 344-Livingston, state insurance fund.
Int. No. 432-Byrnes, physiotherapy.
Int. No. 451-Gimbrone, occupational diseases.
Int. No. 492-Theodore, free choice surgeon.
Int. No. 575-Esmond, psychiatric clinics.
Int. No. 584-Moffat, occupational diseases.
Int. No. 785-Coughlin, occupational diseases.
Int. No. 786-Coughlin, free choice.
Int. No. 980-Story, occupational diseases.
Int. No. 1030-Gimbrone, sale of habit-forming drugs.
Int. No. 1462-Foody, sale of methanol.
Int. No. 1464-Gimbrone, free choice.
Int. No. 1687-Kahan, medical inspection of school children.
Int. No. 1723-Doyle, broadcasting medical terms.
Int. No. 1855-Cornaire, fibrosis due to silica dust.

* * * * *

On Wednesday the Wicks-Hutchinson health bill was given a hearing before the joint Finance Committees. There was a very large attendance. Before the hearing began the Department of Health announced extensive amendments to the bill, which changed its character very materially. Very little opposition was presented; certain medical men objected to the mandatory phase and the provisions in the original bill made for the treatment of venereal diseases, but the amendments, which provide that venereal disease treatment should be accorded only those who are unable to pay a private physician, had removed most of that objection. Representatives from two county boards of supervisors also appeared in opposition to the bill. Probably more than a score of organizations had representatives there to speak in favor of it. The bill still rests with the Finance Committees. The Assembly Ways and Means Committee has just been accorded the privilege of continuing its deliberations to the end of the session, instead of being obliged to give up its bills to the Committee on Rules, as is the custom of the other Assembly committees ten days prior to adjournment.

BULLETIN—MARCH 23, 1931

To County Society Legislative Chairmen:

Enclosed you will find the following bills:

Late Print No. 2293 of Assembly bill Int. No. 817—Mr. Story, to amend the Penal Law in relation to clinics in hospitals. You will notice that the bill has been amended so that it shall apply only to clinics that may be hereafter established.

There is also enclosed a copy of the hospital licensure bill in which we were so interested last year, amended and introduced in the Senate only.

Int. No. 1617—Mr. Byrne. The object in having the Bill introduced this year was simply that it might be printed and an opportunity given us to study it during the coming year. It will not be advanced.

Very truly yours,

HARRY ARANOW
WALTER A. CALIHAN
JOHN J. RAINEY
Committee on Legislation.

GENESSEE COUNTY

The Medical Society of the County of Genesee held a special meeting on March 16, in Batavia, and adopted the following resolution:

Whereas, His Excellency, Hon. Franklin D. Roosevelt, Governor of the State of New York, did appoint a Special Health Commission in May 1930 to study the Public Health needs of the people of the State of New York and the extent to which these needs are being met under existing legislation, and

Whereas, the Medical Society of the County of Genesee met in special session March 16, 1931 to consider the findings and recommendations of said Commission, and

Whereas, we, the members of the Medical Society of the County of Genesee, have repeatedly gone on record as favoring home rule, and

Whereas, we are of the opinion that free medical service, regardless of the individual's social standing, lowers public morale and encourages pauperism, therefore, be it

Resolved, that it is the consensus of opinion of the Medical Society of the County of Genesee, in meeting assembled this day, that the recommendations of said Special Health Commission violate the principle of home rule, and be it

Resolved, that this Society, with the exceptions stated below, hereby protests the enactment of this bill:

(I) We are aware of the urgent need of immediate legislation to provide for the building of additional sanatoria for the treatment of all forms of tuberculosis and are, therefore, thoroughly in accord with this recommendation.

(II) We feel that the New York State Institute for the Study of Malignant Disease, situated at Buffalo, N. Y., in the County of Erie, known also as the Gratwick Laboratory, has in the past, and is now, rendering admirable service to the community in research, diagnosis and treatment of cancer. We approve of additional State Institutions of this type.

FRANK R. HALL,
Secretary.

RENSSELAER COUNTY

A regular meeting of the Medical Society of the County of Rensselaer was held on the evening of March 10 at 8:30 P. M., at the Troy Hospital. The session began with the following scientific program:

Dr. M. E. De Luca—Ruptured Gastric Ulcer.
Dr. J. B. Burke—Foreign Bodies in the Orbit.
Dr. H. V. Foley—Valvular Heart Disease and Complications.
Dr. F. J. Noonan—Acute Cholecystitis and Appendectomy.
Dr. W. T. Diver—Different Types of Goiters.

Dr. Leo S. Weinstein and Dr. Helmar Howd were elected to membership.

The greater part of the business session was devoted to a discussion of the County Health Department feature of the public health bill sponsored by the State Commission on Public Health, as outlined in this Journal of February 15, page 230. The provisions of the law and its scope were introduced by Dr. Wm. B. D. Van Auken, Chairman of Committee to study County Health Law.

Dr. Leonard, President of Sanitary Officers Association of New York State, gave a lengthy talk on several aspects of the bill, including the recent changes effected by his organization.

Dr. Robert E. Plunkett spoke of the advantages of the bill to the medical profession.

The total time of the discussion was about an hour and one-half, and most of the time was taken protesting against its compulsory and economic features. It seemed to the members that the enactment of the bill would be a step towards state medicine. The following resolution was adopted:

WHEREAS an act has been presented in the Senate of New York requiring the establishment of County Health Units which we believe will very materially increase the financial cost of public health work, and

WHEREAS we have not yet found sufficient proof that a corresponding increase in the value of the health service rendered to the taxpayers and inhabitants of New York State, will be obtained by the enactment of this proposed bill, therefore be it,

RESOLVED that the Medical Society of the County of Rensselaer hereby protests the enactment of this bill until further study and experimentation of its provisions are made.

The Health Bill was further discussed at a meeting of the organization of the Medical and Allied Professions held on the evening of March 16, in the health center auditorium. There were present about 20 physicians, 10 dentists, and 40 nurses. The president, B. S. Booth, M.D., presided, and E. W. Briggs, D.D.S., was secretary.

Dr. Booth explained that the organization of Allied Professions had been in existence since the Compulsory Health Insurance Bill was introduced, and that its objects were to bring a united front against destructive health legislation, and to support constructive legislation.

The resolution of the Rensselaer County Medical Society was read. Dr. James F. Rooney gave an address which explained the origin of

the bill, its socialistic character, the more recently proposed amendments, their relation to the dental profession, the obvious provisions of the bill which set up a bureaucracy of health, and the possible ultimate tendency towards the establishment of state medicine.

Dr. Nathan J. Patterson, chairman of the legislation committee of the New York State Dental Society, spoke on the interrelation of the dentist to the medical profession, making clear that what affected one would eventually affect the other. He too, was of the opinion that the bill as presented was a step toward state control of the allied professions. He regretted that no dentist was a member of the Governor's Commission for the study of the public health and the distribution of medical service.

Dr. J. H. Collins of Schenectady and Dr. R. E. Plunkett of the State Department of Health, spoke in favor of the bill. They were of the opinion that a careful study of the bill would show that it was not as harmful as it might appear. Dr. Plunkett stated that he had visited many such county health units in Ohio and with one exception the medical profession at large in those counties were benefited by the county health unit.

At the close of the meeting, which lasted about two hours, a resolution was adopted protesting against the Wicks Bill as printed.

ONEIDA COUNTY

The annual meeting of the Oneida County Medical Society was held on January 13th in the Hotel Utica, Utica, N. Y. A feature of the meeting was the official address of the retiring president, Dr. H. F. Hubbard of Rome, in which he traced the growth of preventive medicine and predicted that the present accelerated growth for the next twenty-five years would result in the elimination of infectious diseases; while the growth of administrative medicine would lead to the distribution of all medical service by the State.

Dr. G. M. Fisher, past-president of the Medical Society of the State of New York, described the recent progress in establishing the principle of the free choice of a physician by an injured workman under the compensation law. Dr. Fisher also urged the wider practice of periodic health examinations.

Dr. Halsey J. Ball, District State Health officer traced the great reduction in the number of diphtheria cases in Oneida County, and also the reduction in scarlet fever cases.

Dr. Richard H. Hutchings, Superintendent of the Utica and Marcy State Hospitals, was elected President. Dr. Hutchings has been a leader in the movement for the early recognition of mental derangements. He has been unusually successful in persuading patients to accept hospital treatment in the early stages of psychiatric troubles.

Other officers elected were:

Vice-President, Dr. E. M. Griffiths
Secretary, Dr. William Hale, Jr.
Treasurer, Dr. H. D. MacFarland
Librarian, Dr. T. Wood Clarke

Members of the Board of Censors: Drs. W. B. Roemer, E. E. Powers, H. F. Hubbard, B. P. Allen, B. L. Rockwell.

Delegates to the House of Delegates, Drs. G. M. Fisher and Hyzer W. Jones. Alternates, Drs. Charles Quinn and Dan Mellen.

TIOGA COUNTY

The regular quarterly meeting of the Tioga County Medical Society was held at the Ahwaga House, Owego, Tuesday, March 3rd. Dr. Silas Molyneaux and Dr. Matthews, his assistant, of Binghamton, N. Y., were the speakers. The following members and guests were present: Dr. W. A. Moulton, Chairman of Candor; Dr. F. Terwilliger, Secretary, Spencer; Dr. Cady and Dr. Brown, of Nichols; Drs. Bailey, Carey and G. S. Carpenter, of Waverly; Drs. Bauer, Peterson, Wilson, Hyde, Capron, Fisher and Beck, of Owego; Dr. H. L. Knapp, Sr., and Dr. H. L. Knapp, Jr., of Newark Valley; Dr. A. Max Fisher, Spencer; Dr. Lyons, of Ulster, Pa.; Drs. Naylor and Noteware, dentists, of Owego; Mr. Harry Tompkins, County Welfare Commissioner and Mr. Leon Baird, Deputy Commissioner were present as guests of Dr. Bauer. Miss Maynard, who is in Tioga County to give a course in Home Nursing, and the County Nurses Miss Agnes Oldfield and Miss Elizabeth Pinney were also present. Mrs. Leslie Fancher was the guest of Dr. Hyde.

After a short business meeting, Mr. Tompkins spoke to the group on the "Hospitalization of County Cases." Dr. Molyneaux gave a very interesting talk on the "Diagnosis and Treatment of Conditions in the Abdomen." Dr. Matthews followed with a paper on "Jaundice." Many questions were asked and interesting discussions followed both papers.

A moving picture on the making of lenses for spectacles was shown by Dr. Hyde, the machine being operated by Mr. Francher. This film showed the making of glasses from sand, potash, lime and soda through the various processes necessary to the completion of the finished lenses.

F. TERWILLIGER, *Secretary.*

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Elsmere Hall, 170th Street at College Avenue, on February 18, 1931, was called to order at 9 P. M., the First Vice-President, Dr. Smiley, in the chair. Dr. Smiley explained that the President, Dr. Gettinger, was unavoidably absent on account of his being present at the White House Conference on Child Health at Washington.

The Chairman thanked the Committee who had made the arrangements for this meeting and welcomed the members to the new meeting hall.

The following candidates were elected to membership: Drs. Joseph Blasenstein, Eurelio Giordano, Frank H. Granito, Jacob I. Lamstein, Lewis Palay, Samuel J. Weitzen and Leo Wilson.

Dr. Bick presented the Report of the Social Committee on the Beefsteak Dinner held on January 28th. The profit on the affair is to be devoted to the relief fund.

Dr. Podvin reported on a meeting held at the Academy of Medicine of the Coordinating Committee, consisting of the Presidents of the five County Societies and one additional representative of each County Society. This Committee is the result of the meeting of the State Committee on Public Relations held about a month ago, at which it was suggested that a supplementary Committee on Public Relations be formed. Dr. Ludlum, President of the Medical Society of the County of Kings, was elected Chairman, and Dr. Thomson, of the same Society, was elected Secretary. After enumerating the matters considered by the Committee, Dr. Podvin emphasized the importance of the meeting in that it may be possible to have our problems adjusted by getting united action on the part of the five County Medical Societies.

The Chairman, Dr. Smiley, then elaborated upon the report. He stated that this Committee has the promise of full sympathy and cooperation from the State Society. He concluded by emphasizing the importance of united action on the part of the five County Societies and asked for the cooperation of the members.

The Scientific Program then proceeded as follows:

Paper

The Various Types of Infections of the Urinary Tract in Children (Lantern Slides),

by A. Hyman.

I. J. LANDSMAN, M.D., *Secretary.*

A regular meeting of the Bronx County Medical Society was held at Elsmere Hall, 170th Street at College Avenue, on March 18, 1931, at 9 p.m. with the President, Dr. Gettinger, in the Chair.

Drs. Milton Greenberg, Aaron Kurtsman, Michael M. Marolla and Charles J. Mehlmann were elected members.

Dr. Magid, Chairman of the Committee on Medical Economics, reported that a Fee Schedule for Compensation Cases has been presented to the Committee.

Dr. L. A. Friedman, Chairman of the Committee on Public Health, reported on the matter of diphtheria immunization. The recommendations of the committee to offer to the Commissioner of Health the services of the Bronx County Medical Society to administer toxin-antitoxin, and to cooperate with the Department of Education in the examination of pupils at high schools, were approved.

Action on the resolutions adopted by the coordinating committee of the five county societies and approved by the Comitia Minora, was then declared in order. These resolutions provided that "The Bronx County Medical Society recognizes the principle that the physician must be paid for his service in order to function as a useful and contributing member of society; and that when physicians work in out-patient clinics they should receive remuneration for professional services rendered." It was moved and carried that the Society go on record as approving the resolutions.

The following resolution was adopted by a rising vote:

"Whereas, The Bronx County Medical Society having sustained a severe loss in the death of its honored associate, Stratford F. Corbett, M. D., be it

Resolved, That the Bronx County Medical Society record the sense of its loss in the death of Dr. Corbett and that a minute thereof be placed on the records of the Society.

The scientific program consisted of a paper entitled "Varieties and Treatment of Circulatory Failure," by Marcus A. Rothschild. The paper was discussed by Drs. Alexander Goldman, David Greenberg and Sydney Steiner.

I. J. LANDSMEN, M.D., *Secretary.*

THE DAILY PRESS

Reg'lar Fellers — There's the Rub — By Gene Byrnes

From the New York Herald Tribune, March 13, 1931

BASEBALL LINGO

Doctors have their due proportions of baseball fans who enjoy the peculiar language of the sport page, and in addition every scholar among them will treasure a biographical note connected with the origin of the slang. The New York *Times* of February 13 says editorially:

"Charles Dryden is dead after ten years of invalidism. The public, which he once entertained with an astonishing ingenuity of reportorial style, has forgotten him. His first imitators in sports reporting were conscious of following his lead. But now his jokes and weird tropes and strange periphrastics are embodied in many articles without realization on the part of the authors that Mr. Dryden was the father of their style.

"For some years he wrote about baseball for the newspapers. He never took the game seriously, and his purpose was to entertain his readers while adhering closely to a news account of what happened. He would write thus of an ordinary incident:

"'At this juncture of the proceedings Mr. Napoleon Lajoie, descendant of a Marshal of France, lumbered determinedly to the batsman's place. He shook himself, spat upon the ashen baton of his calling, glared at the pitcher like Polyphemus at Æneas, took a mighty grip upon the quarterstave, swung like a baboon across a tree-top—and fanned, gentle readers.'

"Under Mr. Dryden's influence this sort of spoofing had a great vogue, and many works of fiction are indebted to it for style."

THE SPLINTER AND HEALTH

The New York *Times* of February 24 has this to say editorially about the splinters in compensated accidents:

"Thirty-five splinter accidents a day would seem, at first, a small number for the 7,000,000 people or more of the New York City population district Even though the man of the house goes in for fewer chores than once upon a time with hammer, chisel and knife, there would still be in our degenerate days enough opening up of wooden containers, driving in of nails for clothes and adjustment of tight-stuck windows to account for more than three dozen splinters a day. The mere sharpening of pencils in New York City business offices would foot up more than that, not to speak of glass splinters.

But the State Department of Labor is speaking of compensated splinter accidents. Office workers and heads of families operating hammer and chisel are not under the compensation laws, and even the insured worker must have suffered a splinter accident severe enough to cause a week's idleness. The total compensation so distributed amounted in 1929 to $350,000. Nearly always it is a case of infection following upon a neglected breaking of the flesh and failure to remove the foreign body—the latter a precaution which the uninsured public might well keep in mind."

DEATH BY WAR AND AUTOMOBILE

A comparison of the number of deaths caused by war and by motor cars is frequently the subject of editorials such as the following one from the *New York Times* of March 12:

"A pamphlet on motor-vehicle accidents prepared by the Travelers Insurance Company of Hartford bears the title 'Worse Than War.' In the World War the A. E. F. lost 50,510 men in battle and fatally wounded in eighteen months; in the past eighteen months 50,900 persons were killed by motor accidents in the United States.

"In 28,000 of the fatal accidents in 1930 there was nothing wrong with the vehicles mechanically. Nine out of every ten persons killed during that year were victims of accidents in which the drivers had had more than a year's experience at the wheel. Most of the accidents occurred in clear weather. Sunday was the heaviest casualty day. Forty-two of every 100 fatalities happened in the night-time. Most of the drivers at fault were exceeding the speed limit, driving on the wrong side of the road, or failing to grant right of way. Obviously the inside of a motor car is safer than the street, for 'the deaths of pedestrians amounted to 122 per cent more than the fatalities among the occupants of colliding cars.' "

The editorial writer closes with the impractical conclusion that "users of motor vehicles must be led to feel their responsibility at all times and in all places."

Another editorial writer in the same issue of the *New York Times,* commenting on the discovery in Pennsylvania that 2,000 applicants for motor licenses were blind in one eye, gives his estimate of the defects of Sunday drivers on the Jericho Turnpike, Long Island, as follows:

Total number of drivers	75,000
Blind in one eye	20,000
Blind in both eyes	10,000
Slightly maniacal	10,000
Intoxicated	10,000
Show-offs	10,000
Criminal insane	5,000
Terrified	5,000
Inattentive	4,500
Normal	500

PRIMITIVE WORDS IN MODERN SPEECH

The Lantern Column of the New York *Herald Tribune* of February 7, discusses the modern use of primitive words in a way that is delightfully serious and comic, and says:

"A minister of Perth Amboy, was shocked the other day to hear his little daughter murmuring, over and over, the mystic and sinister words:

'Umfa glug, umfa glug.'

"She had learned the words, she said, from a book taught in the public school—V. M. Hillyer's 'A Child's History of the World.' The good minister investigated and discovered that the work in question is shot through with damnable evolutionary doctrine. It teaches that our cave-man ancestors had hair all over their bodies, that they slept on the ground at night, that they were bloodthirsty and that, worst of all, 'they talked to each other with some sort of grunts—umfa umfa—glug glug.'

"The minister pointed out the heinous passages to the superintendent of schools, who promptly banned the offending book from the curriculum, regarding the two words as peculiarly bestial and degrading, unworthy of *homo sapiens* at however a primitive stage of his development.

"We, on the contrary, regard umfa and glug as two highly expressive, peculiarly human words. 'Glug! glug!' is admittedly one of our favorite indoor noises. And recently at a night club we heard two men, one a Columbia professor and the other a song writer, express their opinions of a blonde who was galumphing around. One said: 'Dumb cluk.' The other said: 'Infra dig.' Combining the two we get something very close to the cave man's verdict: 'Umfa glug!'

"Glug is even easier to justify than umfa. The modest syllable 'ug,' indeed, permeates the whole broad field of human endeavor. The baseball player can slug, the boxer is a pug, the criminal is a plug-ugly or a mug who is put in the jug. Man's eternal passion for gold is symbolized by the nugget, the ecstasies of love are suggested by the hug, and the demon of drink resides in the jug. The mother's endearing words to her child, 'Snug as a bug in a rug,' has a cave-woman sound. We have emerged from the era of the horse (plug) into the machine age (chug, chug)."

BOOK REVIEWS

MEDICAL AND SURGICAL YEAR-BOOK Physicians Hospital of Plattsburg (Vol 1, 1929) Octavo of 322 pages illustrated Plattsburg, N Y, The William H Miner Foundation, 1930

It is a very high order of institutional effort that is set forth in this book Here is a hospital that is able to set up an educational standard which is a model for every other institution of the kind which aims to give a proper scientific account of itself and fully serve the profession and the sick A wide range of topics is ably covered Those responsible for the plan behind the Year-Book and for the Year-Book itself, deserve the highest praise The Physicians' Hospital of Plattsburg is well named and is happily able to fulfill *every* obligation which we assume to be incumbent upon a hospital—not always a realizable ideal A C J

LECTURES ON COLONIC THERAPY Its Indications, Technic and Results By O BOTO SCHELLBERG Octavo of 55 pages, illustrated New York City, The Oboschell Corporation, 1930 Paper, $2 00

The subject of intestinal stasis lends itself to the oretical considerations which if expressed in suitable medical language may seem entirely convincing This handbook is a privately printed publication by a gentleman who bears no credentials or degrees to introduce him to the sanctum sanctorum of medical science And yet the arguments which are advanced seem so well prepared as to warrant the attention of the physician He reiterates the established theories on the subject

The real purpose of the book, however, is to interest the reader in the Schellberg apparatus for colonic irrigation and *these nicely written theoretical dissertations* serve only as a basis for the writer to introduce himself to the medical profession EMANUEL KRIMSKY

ANNUAL REPRINT OF THE REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR 1929 With Comments that have appeared in THE JOURNAL. Cloth Price $1 Pp 81 Chicago American Medical Association 1930

This is the volume in which the Council annually collects the reports on articles found unacceptable during the year This edition contains also several interesting preliminary reports on preparations which show promise but for which the evidence is not yet sufficient to justify acceptance by the Council Reports are given on the products rejected by the Council

NEW AND NONOFFICIAL REMEDIES, 1930 Cloth Price $1 50, Pp 481, xlvii Chicago American Medical Association, 1930

The present edition contains all of the features that have in the past made New and Nonofficial Remedies such a reliable and efficient a guide to the physician who wishes to inform himself on the newer medicinal preparations logical classification of preparations with authoritative articles on each class, complete and carefully written descriptions of preparations elaborate indexes, and a useful cumulative list of references to the literature on articles not accepted by the Council

SURGICAL CLINICS OF NORTH AMERICA Published every other month by the W B Saunders Company, Philadelphia and London Per Clinic Year (6 issues) Cloth $16 00 net, paper, $12 00 net

Vol 10 No 1 February, 1930 (Mayo Clinic Number) This Mayo Clinic issue is as usual most instructive The authors have presented a large number of rare and exceptional cases well worked up, described and illustrated This wealth of selected cases has left little room for summaries of more of the commonplace surgical conditions, which many readers of the Clinics look forward to

Vol 10, No 2, April, 1930 (Chicago Number) This issue contains many valuable papers written by men of exceptionally high standing in the surgical world It is worthy of the closest study

Vol 10, No 3 June, 1930 (New York Number) The New York Number explores many surgical fields, shedding light on various controversial topics The selection of cases is admirable, the illustrations adequate and the presentation excellent

Vol 10, No 4, August, 1930 (Southern Number) The authors of this issue have succeeded in collecting and presenting a series of intensely interesting cases relating to all phases of practical surgery The volume is as usual well illustrated

Vol 10 No 5 October, 1930 (Pacific Coast Surgical Association Number) Most of the leading surgical *clinics of the Pacific Coast are represented in this issue* The selection of topics is excellent and their presentation interesting and clear The authors have very properly avoided the unique in surgery devoting more space to practical considerations of the more commonly met with diseases

Vol 10 No 6 December, 1930 (Philadelphia Number) This issue brings many important surgical observations to the attention of the reader With Deaver, Jackson Babcock and many other prominent names on the contributors' list of the number, its interest and value are assured Malignancies of the large bowel are discussed in detail by several authors Forty pages are *devoted to pathologic fractures almost constituting a* monograph on bone tumors

Besides the above topics which are of interest to every surgeon some highly specialized subjects are discussed as well GEO WEBB.

TEXT BOOK OF EMBRYOLOGY By FREDERICK RANDOLPH BAILEY, A M M D and ADAM MARION MILLER A M, 5th revised Edition Octavo of 687 pages illustrated New York, William Wood & Company, 1929 Cloth $7 00

This book has been entirely revised The section on the development of the nervous system is the most complete *of any text book published* The *section on blood* has been improved by the addition of new illustrations and scientific data An excellent text-book for physician and student H P MCT

APPLIED PHYSIOLOGY By SAMSON WRIGHT M D Second Edition Octavo of 510 pages illustrated New York and London, Oxford University Press 1928 Cloth $5 50 (*Oxford Medical Publications*)

This work is based upon the various courses of lectures given by the author in both the hospital and college departments of the Middlesex Hospital Medical School Throughout the volume stress is laid upon the dictum that *physiology* is one of the *fundamental* medical sciences without a proper knowledge of which one can never be a clinician in the real sense of the word With such a point of view to start with the reader is not surprised to find innumerable references to and discussions of the various human ailments that are the result of disfunction of one or more of the physiologic processes The chapters on the nervous system are excellent as is the section on carbohydrate metabolism which contains an

unusually clear description of the action of insulin on the deranged sugar metabolism of the diabetic.

The book is copiously illustrated and is very well indexed. The volume would be a worth while addition to any physician's library. FRANK E. MALLON.

ESSENTIALS OF MEDICAL ELECTRICITY. By ELKIN P. CUMBERBATCH, M.A., B.M. Sixth Edition. Octavo of 443 pages, illustrated. St. Louis, The C. V. Mosby Company, 1929. Cloth, $4.25.

This is a revised edition of a former work by the same author. It covers very thoroughly the action of electrical currents on the human system. It also describes how the various currents are produced.

The electrical treatment of paralysis has been entered into very thoroughly and the chapter on testing of electrical reactions of muscles covers the entire subject.

The plates showing the proper points for electrical stimulation will be of great help to one in doing this work.

Surgical diathermia is touched upon as is medical diathermia, as static, Faradic, Galvanic and low volt varying currents.

This work should be particularly valuable to the physician wishing to treat neurological conditions.

CHARLES F. McCARTY.

MENTAL ASPECTS OF STAMMERING. By C. S. BLUEMEL, M.A., M.D., L.R.C.P. (Lond.), M.R.C.S. (Eng.). 12mo of 152 pages, illustrated. Baltimore, Williams & Wilkins Company, 1930. Cloth, $2.50.

"A book written primarily for school use but also intended for use by the stammerer who must rely on self-training."

A small book written simply and clearly.

The author properly views stammering as a thought disturbance rather than a speech defect. We speak as we think.

The principles of speech correction and their application are discussed. A chapter is devoted to that very important subject, the proper parental influence, attitude and home environment.

It is a constructive book to place in the hands of stammerers or their parents. L. FEINER.

AIDS TO THE MATHEMATICS OF PHARMACY. By ARTHUR W. LUPTON, M.C., Ph.C. 16mo of 95 pages. New York, William Wood and Company, 1930. Cloth, $1.50.

This little volume contains a number of simplified calculations of aid in the problems encountered in pharmacy. It is intended more to meet the needs of the pharmacist than of the physician. FREDERIC DAMRAU.

A TEXT-BOOK OF GYNECOLOGY. By ARTHUR HALE CURTIS, M.D. Octavo of 380 pages, illustrated. Philadelphia & London, W. B. Saunders Company, 1930. Cloth, $5.00.

The best text-book on gynecology the reviewer has ever read. It reduces gynecology to its simplest form, and makes an otherwise difficult subject easy. It is intensely practical, direct, and free from all the theoretical considerations which so often confuse the student. The general practitioner, anxious to review modern gynecology, and the general surgeon who does pelvic surgery might well read it. The chapters on gonorrhoea and pelvic inflammation should interest gynecologists.

C. A. G.

TROPICAL MEDICINE IN THE UNITED STATES. By ALFRED C. REED, M.D. Octavo of 410 pages, illustrated. Philadelphia and London, J. B. Lippincott Company, 1930. Cloth, $6.00.

The object of this book is to present a serviceable guide to the physician in the U. S. in his contacts with tropical medicine. A surprisingly large area of the U. S. falls within the boundary of hot climate. Wet heat is exemplified the year around in the Gulf and South Atlantic States. Dry heat is found in the Southwest from the plateau region to the Pacific Ocean. Dry or moist hot summers still further extend the range of climatic influence on disease.

Tropical medicine means the application of the principles of alleviation, cure and prevention of disease to disease and to health preservation in hot climates. Tropical medicine thus becomes the practice of medicine in hot climates. The term is not limited solely to those diseases peculiar to hot climates but it takes cognizance of the increasing necessity for civilized man to live there for longer or shorter periods.

In the U. S. many tropical diseases are endemic and serious. Others have a sporadic distribution and may be seen unexpectedly at any time as undulant fever. Others are of occasional occurrence and their recognition is easily missed or delayed because they are not expected. Others may be seen in imported cases.

This volume treats of all the diseases under these headings from all views and angles. To recent medical graduates, to practicing physicians, even to non-medical persons especially travelers, business representatives, missionaries, and nurses, it can be well recommended as a useful clinical pocket guide to the study of tropical medicine. HENRY M. FEINBLATT.

DICTIONARY OF BIOLOGICAL EQUIVALENTS German-English. By ERNST ARTSCHWAGER. Octavo of 239 pages, illustrated. Baltimore, Williams & Wilkins Company, 1930. Cloth, $4.50.

This volume is a German-English dictionary of 15,000 biological terms. Because medical papers frequently include biological terms which can be found in neither the general nor medical dictionaries, the book should be a useful addition to the library of the physician who reads or translates German medical literature.

FREDERIC DAMRAU.

BEHAVIOR PATTERNS OF THE ALIMENTARY TRACT. By T. WINGATE TODD, M.B. Octavo of 79 pages. Baltimore, Williams & Wilkins Company, 1930. Cloth, $1.00. (Beaumont Foundation Lectures, Series No. 9.)

Under this title are collected a series of lectures given by Dr. Todd before the Wayne County Medical Society.

This is a small volume crowded with the most interesting and important basic data necessary in the appreciation and understanding of the functions of the gastro-intestinal tract.

Some four hundred students of the Western Reserve under the careful guidance of Dr. Todd were studied. The response of the digestive system to stimuli of all kinds, both local and central, was registered by means of X-ray study and with serial studies and motion picture reductions. The behavior pattern to such stimuli as water, milk, heat, cold and emotional factors as observed and recorded by the author are not only of interest but of practical significance. IRVING GRAY.

RECENT ADVANCES IN CHEMOTHERAPY. By G. M. FINDLAY, M.D. Octavo of 532 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc. 1930. Cloth, $3.50.

The foreword states "The greater part of the work is necessarily devoted to a study of the action of chemical agents on diseases due to helminths, protozoa and spirochaetes, for as yet little progress has been made in the chemotherapeutic treatment of bacterial diseases, and still less in those of virus infections." This volume deals with "the treatment of parasitic diseases by chemicals with the object of destroying the specific parasites of the disease."

It is devoted to a large extent to tropical diseases, but there are chapters on diseases which are of frequent occurrence in temperate climates, e.g., syphilis, tuberculosis, etc.

This monograph contains a wealth of information on the chemical nature and clinical results obtained with a very large number of substances. A bibliography is appended to each topic discussed. M. J. SHEAR

THE FACTOR OF INFECTION IN THE RHEUMATIC STATE. By ALVIN F. COBURN, M.D. Quarto of 288 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1931. Cloth, $6.00.

Coburn points out the correlation between rheumatic disease and the incidence of streptococcus hemolyticus in the upper respiratory flora of cases observed in the Presbyterian Hospital of New York. A report is made of the work of MacKenzie, Hanger and others which showed positive skin reactions to intracutaneous injections of a hemolytic streptococcus nucleo-protein in rheumatic patients and negative results in normal individuals. This interesting work, the final importance of which remains to be demonstrated, is advanced to show a possible relationship between the streptococcus hemolyticus and the rheumatic state.

The illustrations and diagrams are numerous and well done, but the book on the whole, is verbose and suffers from an overabundance of case histories, some of which might profitably have been shortened or omitted, to reduce the size of the book. Several chapters are devoted to a summary of previous bacteriological work in rheumatic fever and of interesting clinical observations made of the numerous cases of this disease studied in the preparation of the book.

A useful feature is the attention devoted to a somewhat neglected phase of this subject, rheumatic pneumonia. The observations confirm those of Rabinowitz and form an important clinical study of the pulmonary complications of rheumatism.

One cannot permit one statement to pass unchallenged—two cases of adiposity following chorea are reported, with photographs and the statement made that these changes are perhaps an objective indication of cerebral changes, possibly in the region of the hypophysis. In the absence of morphological proof, one would rather be inclined to attribute these changes to the high caloric diet and restriction of activity so often employed in the treatment of chorea and rheumatic states.

MILTON PLOTZ.

OBSERVATIONS ON THE COURSES OF DIFFERENT TYPES OF BRIGHT'S DISEASE AND THE RESULTANT CHANGES IN RENAL ANATOMY. By D. D. VAN SLYKE and others. Octavo of 130 pages, illustrated. Baltimore, Williams & Wilkins Company, 1930. Cloth, $3.00. (Medicine Monographs, Volume XVIII.)

This monograph is a scholarly presentation of diseases of the kidney observed clinically over a period of years upon patients having various pathological renal conditions. The writers follow the classification of Volhard and Fahr, and the recent work of Addis. The types of renal disease are called (1) Hemorrhagic (glomerulonephritis) and (2) Non-hemorrhagic, which includes (a) arteriosclerotic (Nephrosclerosis) and (b) Degenerative (nephrosis, lipoid or amyloid.)

These conditions are carefully reviewed in sixty-six histories illustrating the various steps in the development of the diseased condition.

The monograph is one of the best and most complete presentations upon the subject of nephritis that has appeared recently. It will require careful study but will repay for the time spent on its study. The tables and illustrations are excellent. HENRY M. MOSES.

PRACTICAL APPLICATIONS OF HEREDITY. By PAUL POPENOE. 12mo of 128 pages. Baltimore, Williams & Wilkins Company, 1930. Cloth, $1.00.

This is a small volume written in popular style, and fascinates one because of its intrinsic worth and its easy style. When the reader picks it up, he will not want to stop reading until he has completed the book. The writer is thoroughly conversant with his subject and gives many facts which are not found in the ordinary book on heredity. His remarks on the role of heredity in superior children, in the genius, and in criminals are extremely interesting. This volume is one well worth possessing, as an interesting addition to the more technical books on heredity, which you may already have in your library. JOHN F. W. MEAGHER.

A COMPILATION OF CULTURE MEDIA for the Cultivation of Microorganisms. By MAX LEVINE, Ph.D. and H. W. SCHOENLEIN, M.S. Octavo of 969 pages. Baltimore, Williams & Wilkins Company, 1930. Cloth, $15.00. (Monographs on Systematic Bacteriology, Volume 2.)

This work is the second volume of the Monographs on Systematic Bacteriology, prepared at the request of the Society of American Bacteriologists. It covers a highly technical and specialized field; it is essentially a reference book for the laboratory where bacteria, yeasts, and molds are cultivated.

The authors searched the literature exhaustively and obtained the formulæ for about seven thousand culture media. By classifying varients with the basal media, they reduced this number to about twenty-five hundred. These twenty-five hundred are here given, with all details necessary for their preparation. Each medium is discussed under the following heads: Constituents; Preparation; Sterilization; Use; Added Nutrients; Variants; and References to the original literature.

Naturally the value of such a comprehensive work will depend largely upon the ease with which the investigator can find the formula he needs. The authors have made this book very practical and easy to use, first, by arranging closely related media together; and second, by having no fewer than four complete indices: a Medium Name index; an Author index; a Constituents index; and a Use index. Thus the familiar oleate blood agar of Avery may be found as Avery's Oleate Blood Agar; under *O. T. Avery*; under *Oleate* and also *Sodium oleate*; and finally, under *Influenza Bacillus*.

As a reference book, this work is indispensable to every bacteriology laboratory. ARNOLD H. EGGERTH.

ROSE AND CARLESS' MANUAL OF SURGERY. By CECIL P. G. WAKELEY, F.R.S., Edin., and JOHN B. HUNTER, M.C. Thirteenth Edition. Octavo of 1592 pages, illustrated, with radiographic supplement. New York, William Wood & Company, 1930. Cloth, $11.00.

This text, now in its 13th edition, was initiated in 1898 as a result of the radical changes effected in the practice of surgery by the work of Pasteur and Lister. The style of the book is peculiarly English and this peculiarity is pleasing. The reason for this is that the essentials of any subject are stressed with no names applied to methods or operations except occasionally. For the student this is a distinct advantage.

The 13th edition has been brought up-to-date in every respect even including such recent methods as the Orr treatment of compound fractures and osteomyelitis. Although the book is not a monographic work several authors have contributed to its production. It is a well balanced and comprehensive surgical textbook.

The 13th edition of Rose & Carless well deserves an important place on the bookshelf of the student and surgeon. R. F. BARBER.

OUR NEIGHBORS

TREND OF MEDICINE IN MICHIGAN

The March issue of the Journal of the Michigan State Medical Society contains a stenographic report of the Annual Conference of County Secretaries, held on January 22, in which Dr. Nathan Sinai of Ann Arbor gave an address on the "Trend of Medicine." The doctor said, in part:

"A bird's-eye view of our whole system of medical care brings out the striking point that almost a million and a half individuals derive their livelihoods and, let us hope, their satisfaction in work, from supplying the various medical services. We would expect to find, when we come closer in our view of the system, some cohesion between the members of this great group, some unity of thought, some definiteness of objective, and some likeness in the method of approaching the objective. However, a closer view reveals that almost the opposite of these expectations exists.

"We find that the great group is broken into smaller groups, and that these are set off from each other in what amounts to almost watertight compartments. In one compartment we find the 145,000 physicians; in another compartment, the 65,000 dentists; and so it goes—compartment by compartment. Not only do we find little contact between the compartments, but we also see evidence of antagonism, animosity, and friction between the groups."

Doctor Sinai then discussed the production and distribution of medical science as follows:

"Medicine has been criticized because the distribution of the results of scientific research has not even nearly kept pace with the production. It is a fact that during the past half century the machinery of production has been modernized and speeded up until today the warehouses of medical science are bulging with results that should be made available to the general population. It is also true that in spite of this high rate of production the methods of distribution still involve the use of the ox-cart."

Dissatisfactions among doctors, dentists, nurses, public health workers, and the public are then discussed as follows:

"It is an inexorable law of progress that human movements shall expand until the very expansion itself results in a haziness of objective. This haziness produces, both within and without the movement, a dissatisfaction, and from the dissatisfaction there comes an effort at concentration and an attempt to clarify objectives. The great movement in medical care has apparently reached the stage of dissatisfaction; the evidences are to be seen on all sides. The physician, speaking generally, is dissatisfied. The same is true of the dentist, the public health worker, the nurse, and the public.

"The physician is dissatisfied, on the average, with his income, and with what he terms 'encroachments' by public and private agencies upon his field of private practice.

"The dentist is also dissatisfied with his income and, though to a lesser degree, fears encroachments upon his field of private practice. Generally speaking, the dentist's dissatisfaction is somewhat less tangible than that of the physician. Dentistry as a whole views the criticisms of medicine and is fearful lest it find itself, in a few years, in the same position.

"The nurse is dissatisfied. In the whole economic chain of medical care, it is becoming more and more apparent that the nurse is the weakest link.

"The dissatisfaction among public health workers is two-fold, and concerns itself not so much with personal income as with conditions of work. Public health workers point to the dividends that have accrued from their efforts and are unable to understand why money for the expansion of these efforts is not forthcoming. The complaint is also made against the lack of interesting preventive medicine and preventive dentistry by private practitioners in both fields. As a result of this dissatisfaction one may see that there have arisen two schools of thought in public health. One school, the smaller, holds the view that preventive medicine must be made available to the population by the state; the other school holds the view that this service should come through the private practitioner, as a result of public demand. Even this second view does not place the private practitioner in an enviable position because there is an implied presumption that preventive medicine must be forced upon him.

"Finally, we come to the most dangerous dissatisfaction—that of the public. In this country the only method the public has for expressing a dislike is through the process of legislation. Changes may take place as a result of an orderly progress we call evolution, or as a result of a disorderly or explosive process called revolution. Revolution is never necessary; it is costly, and results in much debris. If we examine the history of any such process we find that the causes were present and observable long before the explosion

(*Continued on page* 440—*adv. xii*)

Increasing the effectiveness of the SALICYLATES...

THE MODERN trend in salicylate medication favors the concomitant use of alkalis, to neutralize the acid toxins of the bacteria of rheumatism, and to lessen the cardiac dilation associated with rheumatic disorders.

The Wm. S. Merrell Company — pioneers in salicylate medication — have carried the principle into practice by combining in one product, natural salicylate with a balanced alkali.

This preparation is available under the name

ALYCIN

Alycin provides the full effect of the natural salt prepared from the natural source—birch oil—and at the same time provides a more effective and safer method of alkalization than is possible from the use of single alkalis.

In colds, influenza, neuralgias, etc., the analgesic effect of Merrell's Natural Sodium Salicylate is enhanced by the alkalizing action of the base, which combats the underlying acidosis.

Write for sample and literature describing this more effective method of salicylate medication.

occurred, and its occurrence was brought about by inattention, wilful or otherwise, to these causes."

Discussing medical insurance, Dr. Sinai said:

"When the demand for medical insurance arose, in the majority of the early systems developed in each country organizations such as insurance companies, lodges, mutual aid associations, et cetera, were already in existence and were powerful both politically and financially. The task of interpreting the demand for insurance fell to these already organized groups, since they had been dealing to a greater or lesser degree with problems of medical insurance. As was to be expected, the plans developed and presented to the medical organizations outraged and medical principles of ethics, practice, and pride. The result was, in most cases, an antagonistic attitude on the part of the profession so that the insurance plans developed bore no imprint of medical thought. However, regardless of the antagonism of the profession, legislation was enacted and the profession was abruptly forced into compliance with regulations in the development of which they had had no hand.

"The process of change, once the systems were adopted, was and still is a very slow one. The best evidence of this is presented by the changes in the British system brought about through nineteen years of effort on the part of the profession. Almost invariably a few months after the medical insurance system has been adopted the medical sentiment has been 'Why were we not prepared?'

"The more recent health insurance legislation bears the stamp of medical thought. The outstanding example of this is the law adopted in France in 1930. In that country the professional groups met the problem squarely, had prepared a program, and, as a result, France today offers an excellent example of a procedure almost exactly opposite to that followed by the professions in Germany and England."

In conclusion, the speaker said:

"The part the professions are to play in the future trend of medical care is obvious. If there was ever a need for professional groups to pause and objectively study movements in medical care, the need is now pressing. If there was ever a need for forgetting petty animosities and energy-consuming antagonisms, within the professions and between professions, the need is here. Changes that take place may be directed by the professions or there is danger that they will be directed for the professions."

PUBLIC RELATIONS IN MICHIGAN

The question of the public and civic relations of physicians is receiving serious attention in practically all the State Societies. The Journal of the Michigan State Society for March reports the following remarks by Dr. B. R. Cobus, Chairman of the Council, before the Annual Conference of County Secretaries on January 22, 1931:

"First there is your relationship to your local public. In these last years it has become a rather favorite pastime of a good many lay writers and too many graduate doctors to write articles slurring the doctor and slurring medicine as it is practiced. It is a sort of revolt against the physician. Much of this is due to the fact that the physician has kept too much aloof from the public. Enthusiastic lay individuals of your community have felt that they must do something for the public in the way of clinics of various sorts. They have taken control of the clinics, of the baby clinics, the tuberculosis clinics and others, and now it is the clinic of mental hygiene. While they have used the doctor, who is the important wheel in the operation of any of these social clinics, they have given him every little opportunity to express himself in regard to the policy. The doctors themselves have been rather largely to blame because they have stayed aloof and have not made the necessary exertion to inject themselves into these groups.

"I would urge you, secretaries of county societies, to do more than you have done in the past to get into these various activities which are going along in your town, and to see if you cannot show the people that you are interested and, by virtue of your profession, intelligently interested in these health activities.

"The other day in Grand Rapids there was a meeting of a group of osteopaths. I was interested to see in the paper that they had sent speakers to several of the high schools, to tell the pupils the advantages of the study of osteopathy and to urge them to take up osteopathy as a vocation. I can't remember ever seeing a similar activity on the part of any one of us. Perhaps we feel that we could not conscientiously urge a young men to go into medicine, that the returns are not commensurate with the money and time expended and the effort which much be given to make a living. And yet I notice that a doctor is always pleased when his son goes into medicine and follows in his footsteps."

—THAT ENDS WELL

YOUR patient begins with a tablespoonful  continues with a teaspoonful  and finally stops it altogether  Surely, there is no clearer way to demonstrate  the therapeutic value of AGAROL  in the treatment of constipation.

Besides, Agarol is so easy to take. No oiliness, no artificial flavoring to get used to. Agarol can be mixed with water, fruit juices, milk, with semi-solid food, used as a salad dressing in place of mayonnaise. Serves you better—serves your patient better.

A supply gladly sent for trial.

AGAROL is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

CONTROL in High Blood Pressure Cases

PATIENTS suffering from High Blood Pressure need medical treatment. They should not be subjected to self medication or permitted to decide the dosage or the period of time during which medication should be used.

By using Pulvoids Natrico and Pulvoids Taurophen, the physician insures absolute control of medication at all times.

Many physicians charge an extra fee for High Blood Pressure cases. This permits the supplying of medication, which is not only favorable to the physician but assures control treatment for the patient. Try Pulvoids Natrico for yourself and check its results on the Sphygmomanometer. Fill out the coupon below.

A doctor reports:
Female, 40 years, with 250 Blood Pressure, two months ago and since under careful observation at his private hospital. Used Pulvoids Natrico, one four times a day, with regular diet. Blood pressure taken every day. After two months, blood pressure reduced to 138, or about normal, and has sent patient home. The patient is very well pleased, also the Doctor.

BUDGET OF STATE SOCIETY OF MICHIGAN

The March number of the Journal of the Michigan State Medical Society contains the minutes of the session of the Council held January 21, 1931, at which the following budget for 1931 was proposed:

ESTIMATED INCOME

3,450 Members' dues at $10.00	$34,500.00
Interest Earnings	1,500.00
Reimbursements About	1,500.00
	$37,500.00

EXPENDITURES

Medical Defence—3,450 at $1.50	$5,175.00
Journal Subscriptions—3,450 at $2.50	8,625.00
Rent, Light, Telephone, Power	1,800.00
Annual Meeting	1,000.00
Post Graduate Conferences	3,000.00
Legislative Committee	1,000.00
Printing and Postage	500.00
Council Expense	1,500.00
Joint Committee on Public Health	1,000.00
Delegates to Am. Medical Association	750.00
Stenographic and Clerical Help	3,000.00
Secretary's Salary	6,500.00
Committee Expenses	500.00
Contingent for Society Expense	3,150.00
	$37,500.00

JOURNAL BUDGET

INCOME

Subscriptions	$8,700.00
Advertising	8,500.00
	$17,200.00

EXPENSES

Printing and Mailing	$11,500.00
Editor's Salary	3,500.00
Editor's Expense	900.00
Contingent	1,300.00
	$17,200.00

CHARGES FOR INSURANCE CERTIFICATES IN MICHIGAN

The March issue of the Journal of the Michigan State Medical Society contains a letter from Dr. F. C. Warnshuis, Secretary of the State Society, outlining the suggestion made by the Council that doctors should charge insurance companies two dollars for each blank form filled out for purpose of informing the company regarding the cause of death of insured persons. The communication especially urges all members to refuse

(*Continued on page 446—adv. xviii*)

THEELIN, Female Sex Hormone in Crystalline Form, Now Available

THE specific directing energies of the human body are gradually being brought to light—Adrenalin, Pitocin, Pitressin, Thyroxin, Paroidin, and now, in chemically pure crystalline form, an ovarian hormone which regulates a part of the intricate mechanism of the female reproductive system. The credit for the isolation of this hormone goes to Dr. E. A. Doisy, professor of bio-chemistry at St. Louis University, St. Louis, Missouri. The new preparation has been christened "Theelin" by its discoverer, ("*thelu*" being Greek for the female sex). Its manufacture has been entrusted to Parke, Davis & Company.

The therapeutic indications for Theelin are functional amenorrhea and scanty menstruation. It is also being used in cases of artificial and natural menopause, sexual frigidity, delayed puberty, lack of sexual development, and functional sterility. The ovarian preparations which have been heretofore available have been used in the above-named conditions and in many others with varying degrees of success. Theelin, being the pure principle, can be expected to give distinctly better therapeutic results in any condition in which ovarian therapy seems to be required.

Theelin is carefully standardized. The method of assay was developed by Dr. Doisy and the potency of Theelin is expressed in terms of rat units. Theelin, P. D. & Co., is furnished for clinical use in aqueous solution containing 50 Doisy rat units per cc., and for the present is marketed only in packages containing six 1-cc. ampoules.

The new booklet on Theelin will be sent you promptly on request.

to fill out a blank unless they receive the fee. The letter says:

"Insurance companies have imposed too long upon physicians. They have and are now profiting by reason of the expert opinions and advice obtained from physicians without paying for it. Such imposition should no longer be tolerated. It is estimated that these insurance corporations are receiving approximately a million dollars' worth of opinions and expert testimony from physicians without remunerating the physicians.

"The average doctor fills out about 20 to 50 such blanks a year. Does he relish making a contribution of $40 to $100 per year to corporations?

"Insurance representatives, when a doctor declines to fill out a blank, advance several 'sob arguments': 'The patient or the relative is being deprived of his money,' etc. Do not be persuaded by his argument. A united front and a firm stand by every doctor will cause them to accede to our demands.

"Members when filling out a blank after receiving a fee, should not answer any of the following questions:

For what diseases have you attended the patient?

Has he ever had tuberculosis?

Have any relatives died of tuberculosis or heart disease?

What is his present physical condition?

"If you answer these questions you impart 'confidential information' and become liable for damages through suit by the patient or his estate. Within the year several doctors have been sued and judgments rendered against them for having imparted this confidential information to insurance companies. A release will not protect you in court. You are warned to be careful in the answers you give.

"Please impress upon all your members the imperative necessity of complying with the requests and recommendations contained in this communication.

"By direction of the Council."

ANNUAL REGISTRATION IN MICHIGAN

The Committee of the Michigan State Medical Society to study the question of annual registration, reported favorably to the Council on January 21, as follows, according to the Journal of March:

1. Twenty-two states of the Union require annual registration of physicians. While annual registration was opposed in most of these states when the suggestion was first made, at the present time, after this legislation had been enacted, the

(*Continued on page 447—Adv. xix*)

(Continued from page 446—adv xeni)

members of the profession in these twenty-two states are unanimous in their expressions of the benefits that are being derived from such annual registration.

2. The chief benefits that Michigan will derive from annual registration are:

First, the ascertaining of an authentic, up-to-date list of all physicians duly authorized to practice medicine and surgery.

Second, annual registration will expose unlicensed and illegal practitioners and will enable the Board of Registration in Medicine and the law enforcement officers of the state to institute prosecution against these illegal and unregistered practitioners.

Third, it will enable the state to rid itself of undesirable and unregistered practitioners and will be to the benefit of the public as well as the profession.

3. In view of these and other benefits that the committee perceives, your committee does recommend that the state society approve the plan of annual registration.

NEEDED ACTIVITIES OF THE MICHIGAN STATE SOCIETY

Dr. F. C. Warnshius, Secretary of the Michigan State Society, gave an annual report to the Council on January 21, which was printed in the Journal of March, and which contains the following suggestions regarding the immediate extension of the activities of the State Society:

"1. The completion of the survey that will indicate the distribution of Michigan physicians.

"2. A definite schedule of public meetings in each county, sponsored by the County Society and conforming to the plan of the Joint Committee on Public Health Education.

"3 A series of clinics or conferences, conducted at central regional points, that are devoted to demonstrating prophylactic health measures and instructing our members as to how to definitely render such preventive services to their clientele. Our members are overlooking these opportunities and need inspiration and instruction in order that they may avail themselves of the returns obtainable from this type of professional service.

"4. The appointment of a special committee of nine to be known as the Committee on Medical Service. The duties of this committee to be to gather information and data on clinical services; secondly, to formulate a plan whereby County Societies or groups of societies may establish centralized clinics that shall render medical services to the indigents and to those who are unable to assume the full financial burden of their medical care."

The
"Pomeroy"
Supporting Corset

A good corset, properly made and fitted, not only gives needed support to the vital organs, but moulds the figure to correct and graceful lines.

The Pomeroy is ideal for this purpose, for it is so designed that the uplift is given by the corset itself with no need for additional belt or other contrivances. The intersecting laces give an extra upward and backward lift which further helps the muscles of the abdomen to give the necessary support.

MALPRACTICE SUITS IN MICHIGAN

Two curious malpractice suits were reported to the Council of the Michigan State Medical Society on January 21, 1931, by the Medico-Legal Committee. The Michigan Journal for March says:

"A mother, herself a trained nurse, reported fear of infection of her children from a female school teacher, rooming in her house. The health officer took some smears from the vagina of the school teacher and found many intra-cellular diplococci and on report of his findings to the School Board the teacher was discharged. A few months later, the health officer was sued for an alleged error in diagnosis, this claim being based on the failure of a Detroit physician to find gonococci at a later date and a statement from the pathologist at the State University that no gonococci were found four months later.

"Assuming the correctness of the clinical and microscopical diagnoses which the health officer was able to prove by his slides, the question then is, what is the duty of a health officer in enforcing quarantine in dangerous communicable diseases and whether the School Board should have suspended and not discharged the teacher, and whether action, necessary to the protection of many little girls, would have been taken without violation of professional confidence, unjustifiable in a private physician.

"The whole controversy, which split the good people of this village into two adverse camps, resulted in dropping the suit against the doctor on the reinstatement of the teacher. The doctor wanted to fight for vindication, but wisely decided to let time vindicate him.

"Another case of general interest, arising in 1923, was disposed of in 1930. It involved four doctors and a private hospital. A formerly prominent surgeon asked to operate in a gall-bladder case in this private hospital, took his own sponges thus relieving the hospital, at least in some degree, of legal responsibility for the sponge count. The operating room nurse first reported a sponge as missing, then as found, but there was talk about the hospital and next few days of a missing sponge. The history of the patient for the next few months strongly suggests, to a surgically trained outsider, a foreign body in the abdomen, for the wound kept breaking open.

"Four and one-half months later, another operator opened the abdomen and found a sponge, and with it demonstrated to the family the correctness of his diagnosis. When the case approached trial last summer, the family doctor was dead, the sponge finder also dead, rendering his discovery impossible of legal proof. The operating surgeon had retired from practice and was living outside the United States and Mr.

Barbour arranged a settlement by an insurance company for $250.00."

Dr. F. B. Tibbals, Chairman of the Medical Defense Committee of the Michigan State Medical Society addressed the county secretaries assembled in Annual Conference on January 22, on the subject of Medico-Legal Defense. The Journal of February quotes him as saying that the charges in malpractice suits fall into four classes:

1. Competence of the doctor, but this complaint is seldom urged, it being assumed that being licensed by the State of Michigan to practice medicine, the doctor is competent.

2. Negligence is the offence that is usually charged.

3. Non-consent, or assault. A doctor is not "allowed to do things to people medically or surgically without their consent thereto and the charge of an operation without consent therefore is not infrequently brought. This legally constitutes assault."

4. Breach of contract. The doctor is required to display only the ordinary degree of knowledge and skill that prevails in his community, but he must not promise too good results.

There are three general causes for malpractice suits:

1. The dissatisfied patient. "We all have patients in whom our results are not as satisfactory as we hoped for; and so the dissatisfied patient is always present with every doctor.

2. "The second factor is the hungry lawyer. There are lots of men entitled to practice law who are not particularly successful from the financial standpoint and who are, like the struggling young doctor, looking for business of any kind. That class of men I call the hungry lawyers. They are in every community, they are looking all the while for some opportunity to get money out of somebody else."

3. "The third factor is the jealous doctor. If you take the combination of the hungry lawyer, the dissatisfied patient and the jealous doctor, then you have a malpractice suit. This malpractice suit would never have started without the introduction of Factor No. 3. Unless there is in every community some doctor who feels a little sore at Brown, who feels that he should have had this patient, who is a trouble-maker, you never can get that case started. If you once get the case started it cannot succeed in court unless some doctor is willing to take the stand

against the doctor defendant and testify that his treatment was in some way improper."

In conclusion, Dr. Tibbals said:

"Let me call attention to one more thing. We have a lot of cases that are absolutely unnecessary, that are brought as offsets to the doctor's bill. If you and all your members just fix firmly in your minds the fact that we have a statute of limitations in Michigan for adults, of two years, and let over two years go by before you attempt collection of your bills, you will save a lot of trouble."

New York physicans could well give heed to the general procedure of the principles to be followed when threatened with a malpractice suit. The Journal of the Michigan State Medical Society for February gives the following directions for action when a suit is threatened:

"There seems to be considerable misunderstanding as to what course should be pursued when a member is threatened or is sued for malpractice. The Medico-Legal Committee of the State Society will defend every member in good standing through all the courts. In order that there may be no entanglements and that proper legal protection may be given, members are urged to observe the following instructions:

"When threatened with suit or when served with a bill of complaint for malpractice, notice should be immediately given to the Medico-Legal representative of your local county society. Notice should also be immediately given to Dr. F. B. Tibbals, chairman of the Medico-Legal Committee, 410 Kresge Building, Detroit, Michigan, together with all papers or notices that may have been served upon you.

"It is important that a member does not discuss either with an attorney or with the plaintiff any of the facts or details concerning the suit. Pursue a course of absolute silence and await full instructions from Dr. Tibbals. Do not engage any local attorney, but await instructions that will be given to each member in regard to the employment of legal talent. This procedure is absolutely essential and imperative in order that you may be surrounded with the fullest protection.

"Members are urged, when attending fracture cases, to have an X-ray picture made before any attempt at reduction or treatment, and also to have several X-ray pictures taken during the course of treatment and upon the final discharge of the patient. Failure to do so makes procedure for defense difficult.

"Remember, in all suits or threats of suits, to immediately send a full report to Doctor Tibbals."

BAD ACCOUNTS IN OHIO

The March number of the *Ohio State Medical Journal* discusses bad accounts editorially and gives rules for giving legality to a bill. The article says:

"Experience has shown that most of the bad accounts could have been avoided if proper care had been exercised at the start in securing necessary complete and accurate data at the patient's first visit.

"For example, it is a fact that about 75 per cent of the delinquent accounts in the average doctor's ledger are cases whose names are either misspelled, or whose first names are not given, or for whom adequate information is not available.

"Some of that writer's suggestions for the physician or his secretary in their efforts to eliminate delinquent accounts are:

(1) In taking the patient's name, be sure that the surname is correctly spelled and printed out

(2) Always ask for the full first name as well as the middle initials of the patient.

(3) Record the occupation of the patient, or of the patient's husband or parent, as well as the concern where employed.

(4) Record carefully the residence address, and if a business address is available, record both it and the residence.

(5) Take extreme precautions with persons who give a rooming place, or office building as their address. In all such cases find out the permanent home address.

(6) Take extreme precautions with patients who have no telephone at their residence address. Possession of a telephone is a good indication of the patient's ability or willingness to pay his bills.

(7) Get detailed information on all persons who give an out-of-town address. Get cash payment in such cases if possible.

(8) Always ask any new or unknown patient who referred him to the doctor, and record that person's name and address on the ledger card."

A Ptosis Garment

Effective in Extreme Emaciation

External and internal thinness of ptosis patients, increasing the difficulty in correcting the condition, has been considered in the construction of this Camp Ptosis Belt

Hood shaped sections fit snugly over prominent hip bones, releasing pressure at crest of ilium; allowing close contact of support and central abdominal wall. The belt stays put, lying flat In extreme cases, pads are properly inserted. The Camp Patented Adjustment, a feature of all Camp garments, insures ease and quickness of manipulation. The comfort, lightness and flexibility of the garment, and the firm, comfortable uplift it provides has made this an extremely successful garment.

Sold by the better drug and surgical houses.

MEMBERSHIP IN MISSISSIPPI

There seems to be a fairly even proportion of county society members among the physicians throughout the Nation. The proportion in New York State is about 75 per cent. The proportion in the several councillor districts of Mississippi is discussed in the March number of the *New Orleans Medical and Surgical Journal* as follows:

"Comparative figures are always interesting, even though it has been said that 'comparisons are odious,' and with us they give us a fairly good idea as to how effectively the question of organized medicine is being sold in the various parts of the State. Without them we do not know the weak points—where a district contains one or two especially live societies we sometimes get the idea that the whole district is active when such may not be the case.

"These are the 1930 membership percentages:

9th District	77	per cent
6th District	75	" "
3rd District	72	per cent
8th District	72	" "
2nd District	68	" "
1st District	66	" "
5th District	65	" "
7th District	61	" "
4th District	59	" "

"These figures do not truly reflect the activities of the different Councilors and no such suggestion is intended. A live man may have an unusually stubborn bunch of mavericks in his district and certainly no one can blame the Councilor or the 7th District, who has only been in office about four months, but they do show that conditions in some parts of the State are far from satisfactory. These figures are obtained from the roll of members and the lists of eligible physicians that were checked by the County Secretaries."

New York Post-Graduate Medical School and Hospital

offers an eight months' course in

OTO-LARYNGOLOGY

BEGINNING JUNE 1, 1931

Included in the course are: Anatomy and Physiology of the nose, throat, and ear; Embryology, Histology, Pathology, and Bacteriology of the nose, throat, and ear (given by laboratory staff); Dissection of the head and neck; and nose, throat, and ear operations (cadaver); daily clinics in a large out-patient department; Bronchoscopy; Esophagoscopy, etc. ¶ During the last few months the matriculate performs under supervision a number of the more common nose and throat operations in the out-patient department. ¶ Laryngology under the direction of Dr. Duncan Macpherson. ¶ Otology under the direction of Dr. Warren C. McFarland. Licensed physicians in good standing are admitted to these courses. A combined course in Ophthalmology and Oto-laryngology of 12 months (Ophthalmology, 4 months; Oto-laryngology, 8 months) may be taken by beginning the course in Oto-laryngology June 1, 1931, and the four months' course in Ophthalmology February 1, 1932. ¶ For further information, address

OLLECTION AGENCY IN DELAWARE

The February number of the *elaware State Medical Journal* ntains the following editorial on e collection bureau run by one the county societies:

"The report of the Committee 1 the Physicians' Credit Bureau the New Castle County Medical ociety, which was presented to e Society last month, was not ie to impress an economist or rill a medico. In brief, it showed at approximately $1,100 had en collected out of some $26,000 orth of claims placed with the ureau; in other words, after a ear's efforts, only four per cent f the claims had been collected.

"It was evident to some of the iembers, and in fact, to some of ie committee, that neither the ype of organization nor the meth-ds proposed could reasonably be xpected to be successful."

The editorial says that the Com-ittee of the society "will con-der most seriously the so-called Memphis Plan' the essentials of hich are: a credit bureau incor-orated, owned, and operated by ie Society; a trained credit man-ger in full charge, with trained, onded collectors 'on the street'; membership fee of perhaps $35 or the first year (present service osts $60), with diminishing fees s the bureau becomes better es-ablished; commissions to the bu-eau probably not to exceed 35 er cent in any case, and in most ases only 15 per cent; and a ham-ier and tongs policy that makes ie debtor respect the doctor and is collection bureau. This plan as performed wonders in Mem-his, Birmingham, and Washing-on; and while Wilmington may ave more than its share of con-irmed dead beats and hard-boiled ggs, the experience of other cities ives assurance that the returns vould be many times the four per ent return of the present plan.

"The secret of the success of he 'Memphis Plan' lies in its em-loying only trained, competent vorkers, who can make a decent iving for themselves.

ECONOMICS OF DOCTORS IN KENTUCKY

The March number of the *Kentucky Medical Journal* opens with the following article on the economic status of the physicians of Kentucky:

"This period of general depression, upon which a terrible drought has been superimposed, presents complex problems for solution. No other self-respecting, self-sustaining group, unless it be the farmer and miner, has suffered more injury during this period than the medical profession The Editor of the Journal has heard heart-rending stories of privation from doctors and doctors' families in recent months. In previous disasters, not only in this country, but in lands beyond the sea, similar conditions have been ameliorated by the familiar historic record of the Red Cross, which has provided not only food and clothing, but medical supplies and service.

"Even in this crisis the medical profession in Kentucky maintains its firm conviction that the practice of medicine is inherently an individual responsibility. We are opposed to the state practice of medicine We believe that every individual should be free in the choice of his physician for personal services. We believe that every private practicing physician should receive his compensation from his patients in proportion to the services rendered. We are opposed to the panel system or any other form of socialism in medicine.

"While maintaining these principles and demanding their protection, we realize that there are certain public problems in medicine for the solution of which official organizations must be maintained by appropriation, Federal, State and local. Among these are the care of the delinquent, the insane, the defective and the criminal, and those broad community problems which are recognized under the general title of public health.

A COD LIVER OIL CONCENTRATE OF MORE THAN VITAMINS

Within the last few years the attempt to overcome the unpleasantness of cod liver oil without sacrificing its therapeutc value has been met to a great extent by the development of the so-called concentrates of the non-saponifiable fraction containing Vitamins A and D in varying amounts. Such concentrates, however, do not contain many of the other principles in cod liver oil to which a large number of competent observers ascribe at least part of its therapeutic values. These are, for instance, asellin morrhueine, the organic iodine phosphorous and bromine compounds, etc. It is worth noting, therefore, that there exists a concentrate of the whole oil known as morruhuol. Morruhuol is prepared by a process through which only the oily excipient is removed, the vitamins and also all other therapeutic principles of cod liver oil are retained in fixed proportions. Therefore, because Morruhuol represents the therapeutic concentrate of a definite oil in a definite ratio one can prescribe this preparation with the full confidence that the patient is getting exactly what he would get from a high-grade oil itself. The concentration is such that two capsules are the equivalent of 1 teaspoonful of high-testing oil. Samples and complete literature will be furnished on request by the Laboratoire de Pharmacologie, 92 Beekman Street, New York City. See page xviii.—*Adv.*

DIVERTICULA OF THE OESOPHAGUS*

By FRANK H. LAHEY, M.D., BOSTON, MASS.

DIVERTICULA of the oesophagus are divided into two groups, one, the traction diverticulum, described first in 1840 by Rokitansky; and pulsion diverticulum, described first in 1767 by Mr. Ludlow. Traction diverticula are always in the oesophagus itself. They are usually found on the anterior wall of the oesophagus and most commonly at a level corresponding to the bifurcation of the trachea. They occur at any age. They are characterized by a funnel shape as shown in the illustration, Number I. They rarely cause any serious symptoms during life due to the fact that the end of the sac is usually directed either upward or at least horizontally and rarely downward, and due also to the fact that the wall of the diverticulum consists of all the muscular coat of the oesophagus and so the sac readily tends to empty itself and does not accumulate material in it as does the pulsion type and so produce symptoms.

Because these diverticula cause but few symptoms, a discussion of treatment is not necessary except to mention that when they do cause symptoms, they are usually midly obstructive in character and can be overcome by dilatation of the oesophagus with olive-tipped bougies. It is obvious that being within the chest cavity, it is not feasible to apply surgical procedures to this traction type of diverticulum and also, fortunately, it is not necessary.

Pulsion diverticula, on the other hand, are not located in the true oesophagus, but are located at the junction of the pharynx and oesophagus and so have been termed pharyngo-oesophageal diverticula. They are always located at the pharyngeal dimple, a weak point in the posterior wall of the pharynx just below the transverse fibers of the inferior constrictor and within the two sets of oblique fibers which come off from the inferior constrictor, the crico-pharyngei.

It is probable that this muscular arrangement has considerable to do with the development of these pulsion diverticula which occur so constantly at the same level opposite the cricoid cartilage, always rising from the posterior aspect of the pharyngo-oesophageal junction, and usually with their sacs directed toward the left side.

One recalls that the process of propelling food from the mouth to the oesophagus consists of the contraction of the constrictor fibers until the bolus of food is propelled into the oesophagus. It is probable that the cause of a bulging of the mucous membrane through the point marked "x" on illustration number V is a result of neuromuscular incoordination whereby the inferior constrictor fibers force the food onward, but the oblique crico-pharyngei fibers, shown in illustration V, do not relax to permit the food to pass on into the oesophagus. This, then, results in a bulging through the pharyngeal dimple, the weak point between the oblique fibers of the crico-pharyngei marked "x" in illustration V. At least, insofar as any information we have up to the present time, this is the most probable cause of the mechanical production of these pulsion diverticula.

When the pouch protrudes from this weak point in the posterior wall at the junction of the pharynx and oesophagus, it usually is directed toward the left side, and since the oesophagus is situated between the prevertebral and pretracheal fascia, so the sac of the diverticulum as it bulges to the left side is located just in front of the prevertebral fascia and behind the pretracheal fascia. The location of the sac as relates to the prevertebral and pretracheal fascia is of surgical importance, as this has a great deal to do with the high percentage of fatalities which follow one-stage operations on those lesions. When leakage occurs, it extends between these two fascial planes into the mediastinum and produces thus a fatal mediastinitis.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1930.

It is due to the fact also that the sac of the diverticulum is located in front of the prevertebral and behind the pretracheal fascia that the enlargement of these sacs is directed downward into the mediastinum, and this accounts for the occasional occurrence of the enormously dilated sacs, as shown in illustration number IV, located so deeply in the chest, being guided into the mediastinum by downward extension between these two fascial planes as the sac gradually descends and enlarges.

One observes symptoms in oesophageal diverticula of the pulsion type in relation to the size of the sac. The symptoms are quite in contradistinction to those of traction diverticula. The wall of the oesophageal pulsion diverticulum does not possess the musculature

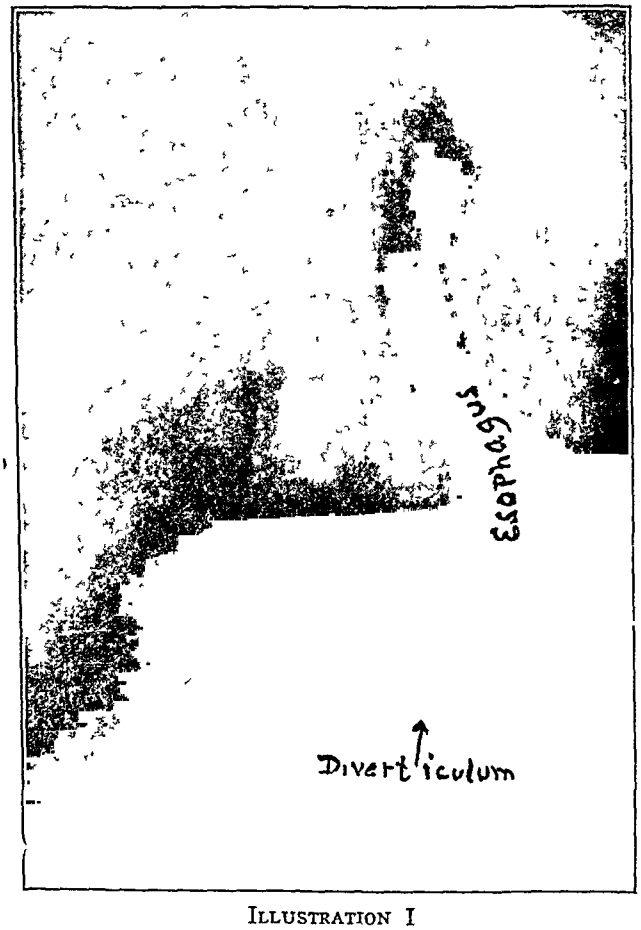

ILLUSTRATION I

This is a typical traction diverticulum. Note that the direction of the diverticular sac is slightly upward or horizontal so that food does not tend to accumulate in the sac. Note that the level is at about the level of the bronchi.

fibers of the oesophagus, the sac does sag downward, so that its lowest point is lower than its entrance, and so tends more and more to accumulate fluid and food, thus producing symptoms from its earliest origin.

The earliest symptoms of oesophageal diverticulum are those which go with the very small sac, as shown in x-ray illustration number II. It will be noticed in this x-ray that the sac represents no more than a small bulging through the posterior wall of the pharynx with the accumulation of but a small amount of bismuth in it. In diverticula of this type, the earliest symptoms are the accumulation of small amounts of mucus and food in such a sac as this, for which the patient not infrequently hawks for a considerable period of time in an endeavor to empty it. Not infrequently at this stage of the diverticulum development there is a complaint of a foreign body, or a scratchy feeling, in the throat. Not infrequently there is present considerable salivation and at times a choking sensation. Due to the fact that small particles of food lodge in this small sac there is a fear of swallowing because of the feeling that food may stick in the patient's throat. These are the symptoms

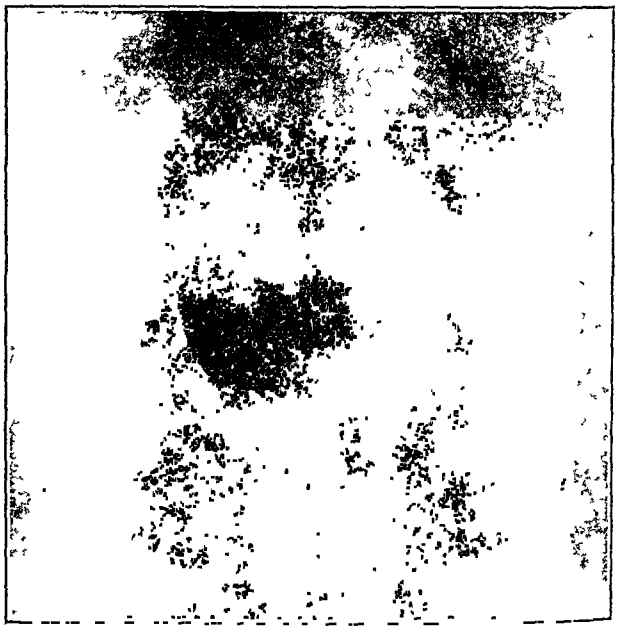

ILLUSTRATION II

This is an x-ray of the earliest stage of oesophageal pulsion diverticulum. At this stage the sac has no neck and consists only of a bulging of the oesophageal mucosa and submucosa through the pharyngeal dimple. It is unwise to attempt operation at this early stage: one, because the symptoms at this early stage are insufficient to justify removal and two, because the size of the sac is so small that it does not lend itself to two-stage removal

which are associated with the earliest types of oesophageal diverticulum.

When the sac has reached sufficient size, illustration number III, to hold considerable fluid or food, symptoms then become of a much more definite character. These symptoms consist of the sticking of large particles of food, then smaller particles, until finally semi-solids and liquids enter the sac and distend it, and

eventually, when the sac becomes large enough, produce complete obstruction, illustration number IV.

The obstruction which occurs in oesophageal diverticula is at first in some measure due to the distension of the sac, but eventually is largely due to the fact that the enlarged sac pulls the lateral opening into the diverticulum downward, converts it into a transverse open-

ILLUSTRATION III

This is a small but fully formed sac. Sacs of this size produce definite and often troublesome symptoms for which removal is indicated. The removal of small diverticular sacs of this size by a two-stage procedure presents certain technical difficulties, a plan for the overcoming of which is described in the technical article referred to in the text.

ing, and makes the true opening into the oesophagus a narrow slit-like orifice laterally located, into which food does not pass readily, but tends, rather, on descent to pass first and more readily into the oesophageal diverticulum. When the sac has attained sufficient size, as in illustrations number III and IV, food which has been taken at a previous meal is always returned, although at irregular intervals and more at one time than another. Patients with these diverticula are often able to so press upon the sac that they can expel the food which has accumulated within the sac. They often complain of gurgling noises due to the mixture of air, fluid and food within the sac which is moved about by motions of the head. One should recall that the regurgitated material from the sac does not contain hydrochloric acid and may thus usually be differentiated from vomitus. X-ray, as shown in illustrations numbered III and IV, characteristically demonstrate the pulsion oesophageal diverticula as to their size, location and shape. It will be observed in the x-rays, illustrations

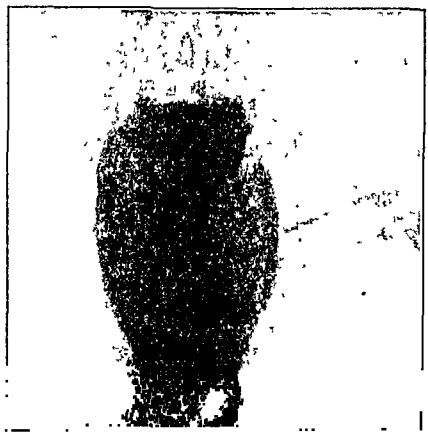

ILLUSTRATION IV

This is the fully developed oesophageal pulsion diverticulum which has extended partly into the mediastinum. This is the stage of diverticular development at which troublesome symptoms are present and at which operation is urgently demanded. This is also the stage at which the diverticulum lends itself well to the two-stage procedure permitting implantation of the sac into the wound with its dome well above the skin level and making the second stage removal easy and satisfactory.

III and IV that the location of the neck of the diverticulum is always constant. It is always opposite the level of the cricoid cartilage, always originating from the pharyngo-oesophageal junction, and the sac always descending downward, usually of a spherical or pear-like shape, occasionally drawn out into the shape of a finger of a glove. A definite fluid level will always be seen at the top of the sac, and the narrowing of the sac as it approaches the opening into the oesophagus will quite constantly be observed. There is no other picture in the neck shown by bismuth x-ray which even simulates pulsion oesophageal diverticulum, and the lesion may be accurately diagnosed by means of the bismuth x-ray.

There are but two methods of treatment for pulsion oesophageal diverticulum One, in the early stages of the diverticulum, oesophageal dilatation, not infrequently makes these patients quite comfortable. During the stages when the sac is relatively small, the opening

of the oesophagus being largely transverse, olive-tipped bougies may be passed without difficulty and dilatation at the neck of the sac not infrequently makes it possible for these patients to swallow much more easily. We have seen a number who have been kept comfortable for a good many years by this method. Its disadvantage is, however, that the sacs are left in place, they still increase in size, and the patients are increasing in years, so that when the operation becomes eventually necessary—as it will in a great many instances—the patients are poorer risks than they would have been had the sac been removed at an earlier stage in their life.

The other method of treatment must of necessity be solely surgical, consisting of the removal of the sac.

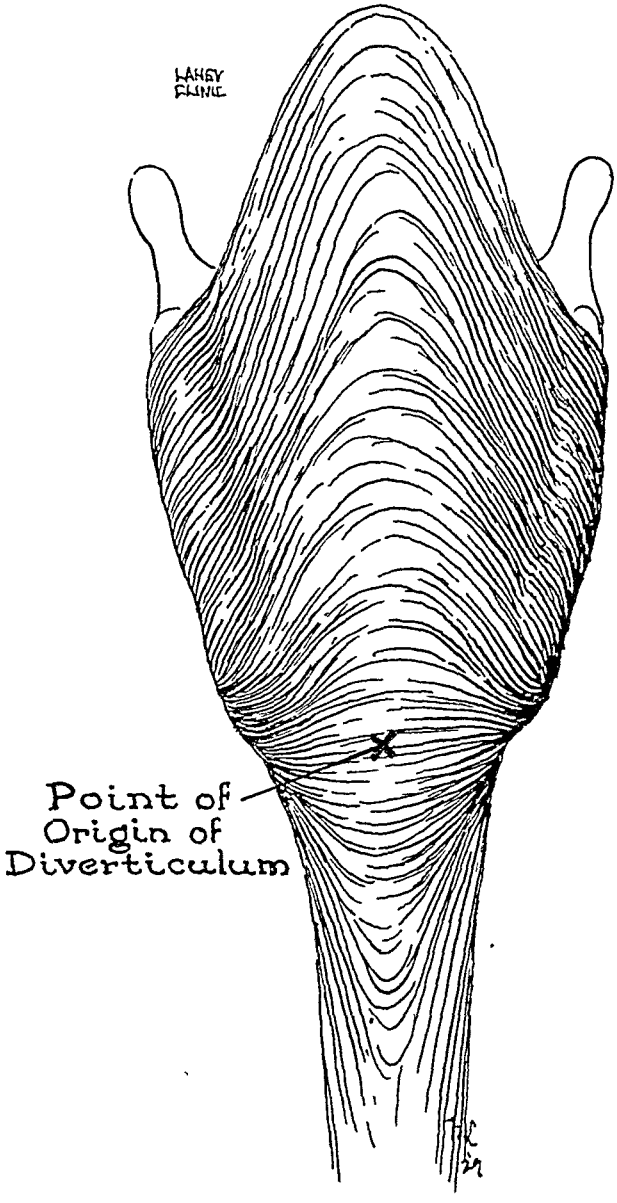

ILLUSTRATION V

This is a diagrammatic illustration of the posterior wall of the pharynx showing the transverse fibres of the inferior constrictor and the oblique fibres of the cricopharyngei. X marks the weak point between these transverse and oblique muscles called the pharyngeal dimple through which the bulge of oesophageal mucosa and submucosa takes place to form the pulsion type of oesophageal diverticulum always at the same level; always at the same point on the posterior pharyngeal wall.

ILLUSTRATION VI

This illustration diagrammatically demonstrates the posterior position of the sac in relation to the oesophagus and the relation of the neck of the sac to the cricoid cartilage.

We have now operated on twenty-seven patients for pulsion oesophageal diverticulum. The average age of the group has been fifty-eight years, their ages being as follows: 42, 42, 43, 46, 46, 48, 48, 51, 52, 54, 55, 55, 59, 60, 60, 61, 62, 64, 65, 67, 68, 70, 70, 72, 76, and 80. All of these patients are swallowing quite well. Three or four require the occasional passage of olive-tipped bougies. All were operated on in two stages. A majority have been done with local anaesthesia. There has been no mortality.

As relates to the operative plan of management of oesophageal diverticulum, it is evident that the operation itself must excise the sac of the diverticulum in order to relieve the patient of the symptoms. All of the early operations for oesophageal diverticulum consisted of exposure of the sac through a lateral incision in the neck, excision of the body of the sac, suture of its neck with catgut, and the in-

troduction of a drain. As stated earlier in the paper, the danger of this procedure is that of leakage, the leakage tending to extend down along between the planes of the prevertebral and pretracheal fascia, from which tract the sac has been removed. When leakage occurs along this tract, as is frequently the case in one-stage procedures, a fatal mediastinitis follows. It was this fatal mediastinitis that produced such a high mortality in early cases when the sac was excised and sutured, in the one-stage procedure.

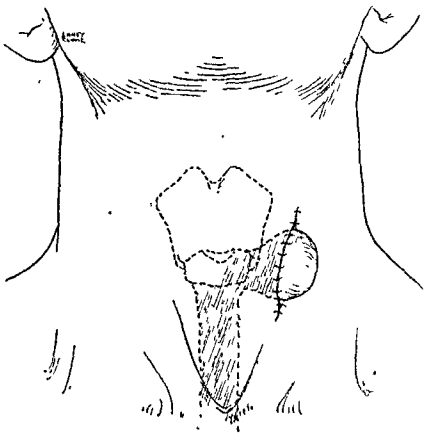

ILLUSTRATION VII

This illustrates diagrammatically the principle of the two-stage removal of oesophageal pulsion diverticula. The sac has been completely dissected from its bed behind the oesophagus. The angulation so constant at the neck of the sac has been dissected clear and the sac has been so implanted in the wound that its dome is higher than its neck and so food does not tend to accumulate in it between the first and second stages of the operation.

It is a well-known fact that primary suture of the oesophagus not infrequently does not result in first intention healing. When one realizes that the oesophagus is filled with infected material and that as the result of swallowing it is constantly in muscular motion, it is understood why primary suture at this location often fails and leakage occurs.

Some years ago a plan of two-stage removal of the oesophageal diverticula was described by Edwin Goldman, providing a method which overcomes practically all of the dangers of leakage, and, at least so far in our hands, has eliminated all of the mortality of this operation.

The plan of two-stage prodedure is shown in illustrations numbered VI to IX, and consists of exposure of the neck of the sac through a lateral incision in front of the left sternomastoid, complete dissection of the wall of the sac, great care being taken not to open it, the implantation of the dissected sac in the wound, the dome of the sac being higher than its neck, so that foods and fluid will not accumulate in it, and closure of the wound about the implanted sac. This sac is allowed to remain in the wound for ten to twelve days until complete healing has taken place about it, and complete obliteration of the fascial planes in the neck has occurred. At the time of removal of the sac, if it is a large one and leaves behind it a deep cavity in the mediastinum, a cigarette drain is also inserted into the mediastinum

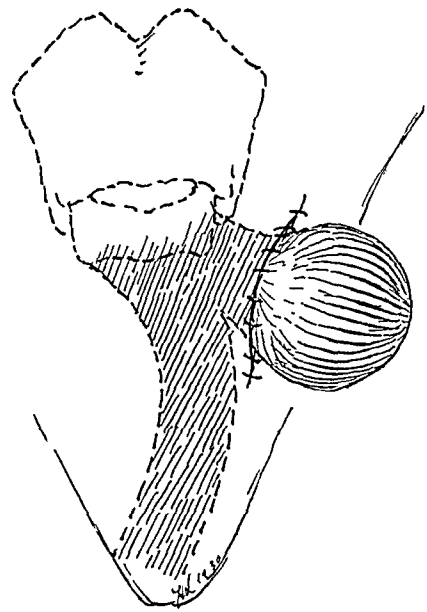

ILLUSTRATION VIII

This shows the serious errors in the two-stage surgical management of oesophageal pulsion diverticula. Note first that so much of the oesophagus has been pulled out into the wound that the oesophagus is angulated and often obstructed. Second that the sac of the oesophagus has not been sufficiently dissected at its lower angle, resulting in its implantation in the wound so that food is directed into it between the first and second stages, producing thus often distension and necrosis of the sac. This failure to dissect the neck of the sac and implant the dome of the sac high produces a partition following the second-stage removal, along which food is directed keeping the sinus in the neck open a long time after removal of the mucous membrane at the second-stage procedure.

cavity to hasten the formation of protective granulations so that, should leakage occur at the second stage, there will be no danger of ensuing mediastinitis.

It is unnecessary to go into an explanation of the technical steps of the operative procedure, a recent description of which, by the author, will be found in *Surgery, Gynecology and Obstetrics* for August, 1930, Volume LI, under the title of "The Surgical Management of Pharyngo-Oesophageal Diverticulum Based upon an Operative Experience with 21 Cases," and the illustrations numbered VI to IX depict the plan of the two-stage procedure.

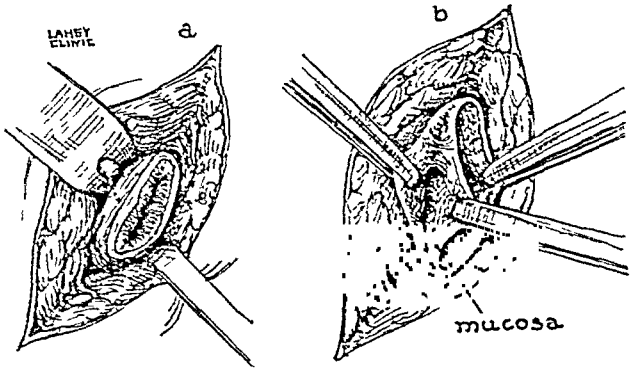

ILLUSTRATION IX

This shows the diverticulum sac cut off in the wound and the mucosa being separated from the submucosa. This separation is carried out almost down to the diverticular open into the oesophagus and the mucosa cut off. The non-mucous lined submucosal canal is then packed with boric ointment gauze and allowed to close by granulation which it usually does within two weeks if the sac has been implanted high in the neck so that food does not escape down its canal.

In large diverticula the sac can be cut off flush with the skin and the mucosa separated from the submucosa without opening the wound.

Following the removal of oesophageal pulsion diverticula, one should always remember that the scar which results from excision of the neck of the sac and cicotrization at the neck will produce a certain amount of distortion of the upper oesophageal canal. It will also produce in the beginning a little difficulty in swallowing and for several months the patient should be instructed to return at first, once every five weeks for two or three months, and then every two to three months for a year, for dilatation of the oesophagus with olive-tipped oesophageal bougies.

We have learned from our experience in bougieing these patients postoperatively that there is considerable distortion of the oesophageal canal and so it is difficult to readily introduce the olive-tipped bougie past the point of operation. One should be careful never to forcibly introduce the bougie, as the point of the bougie may not be directed along the oesophageal canal, but against the wall of the oesophagus, and excessive pressure may well produce oesophageal rupture and a fatal cellulitis. We have never seen this happen, but with some of our experiences in dilating these cases post-operatively we can readily appreciate that it could happen. For this reason, we urge that when these patients' return for oesophageal dilatation, they should be instructed to swallow a piece of silk string two days previous to their visit for dilatation, upon which can be threaded the olive-tipped bougie, which will guide the bougie readily by the obstruction when tension is made upon the string.

Conclusions

There are two types of oesophageal diverticula,—traction and pulsion.

Traction diverticula do not require operation. Pulsion diverticula usually eventually require operation. One-stage operations for pulsion diverticula are dangerous. Two-stage operations are safe and do not require a long stay in the hospital.

Pulsion diverticula should be bougied for several months post-operatively, and bougies should not be passed except when guided by a previously swallowed silk string.

ADDRESSING LAY ORGANIZATIONS ON THE HEALTH EXAMINATION

By C. WARD CRAMPTON, M.D., NEW YORK, N. Y.

From the Committee on the Periodic Health Examinations of the Medical Society of the State of New York, C. Ward Crampton, M.D., Chairman, New York; Luzerne Coville, M.D., Ithaca; W. Warren Britt, M.D., Tonawanda; Frederic C. Conway, M.D., Albany; Marion C. Potter, M.D., Rochester; Walter D. Ludlum M.D., Brooklyn; Guy H. Turrell, M.D., Smithtown Branch; Nellis B. Foster, M.D., New York City; Walter A. Calihan, M.D., Rochester.

THE general Federation of Women's Clubs of the Parent-Teacher Organizations of New York State are sending a message to their local membership clubs throughout the whole State requesting to hold one or more meetings on the health examination for women. They also are requesting them to apply to the Medical Society of the State of New York for speakers on this subject. In response to these requests the following notes and suggestions for medical speakers have been prepared by the Health Examination Committee of the Medical Society of the State of New York. The outline is in two parts:

1. The address itself.
2. The Scientific Background of the Speaker.

PART I—THE ADDRESS

Importance of the address:—You, the speaker, have been asked to discharge one of the most important functions of organized medicine,—to give competent authoritative helpful advice to the public.

You represent the state and county societies, but even more, the age-old service of the doctor to the people. You have an important duty. In some respects it is new. It will do good, it may save lives. You are a personal representative of all of us. You are now the authority.

With all of our good wishes behind you, represent us with modesty, confidence, dignity and power.

Preparation.—Prepare your speech. Write it out, if possible, and rehearse it aloud beforehand. Many of the best speakers do this. Do not read from the manuscript too closely, if at all.

Speak twenty minutes. (A prominent minister once said about sermons:—"Very few souls are saved after the first twenty minutes.")

Have it understood that you will answer questions afterward. If you have your audience with you, you can then give them a few minutes more. Always less than they want, never more.

The Chairman's Introduction:—What the Chairman has to say in her introduction is important. Write out for her what you wish her to include, which will probably be the following:—

1. The importance of the speech.

2. The General Federation of Women's Clubs, and the Parent-Teacher Association of New York State have, in a State conference, passed approving resolutions.

3. The medical auspices should be stated, i. e., surely your own County Medical Society, possibly the State Society, if convenient.

4. Your own name, stated as a practising physician who has given special study to this subject.

5. Ask the chairman not to embarrass you by making your introduction laudatory.

Advance Notice:—A good advance notice in the public press will swell the audience and increase the results of your talk. Confer with the President or Secretary of your County Society, or the responsible publicity officer. Confer also with the person who has invited you and arrive at a conclusion as to the proper method of getting your notice in.

If it can be done, see to it that the following elements are included:

1. The exact hour and place.
2. The organization that holds the meeting, the speakers and the important points on their program, some interesting item of news in connection with the matter, and the title of your address.
3. Who are invited to attend?

Report of the Meeting:—If agreeable to all concerned, have a reporter present and see that he has the following in his notes:

a. Credit to the Women's organization, local and State.

b. Mention of the auspices of the County Society is essential.

c. The fact that there is a state-wide campaign, however, makes good "news."

d. Select one or two of your more important statements. Have them typewritten and see that they get to the reporter for verbatim quotation.

Title of the Address:—The following titles are suggested:

1. "Health Examinations for Women." This is matter-of-fact but uninspiring.

2. "The best health insurance for children," i. e., keep father and mother alive and well for the children's sake.

3. "Nature's warnings are too slow," i. e., pain does not warn in time in tuberculosis, cancer, nephritis, diabetes, etc."

4. "A stitch in time,"

5. "A new medical idea,"

6. "The Chinese Doctor,"

7. "Prophetic Medicine,"

8. "What Brains are for,"

9. "This Day's Madness," i.e., the quotation from Omar Khayyam, "Yesterday, this day's madness did prepare."

These titles illustrate the value of foresight, and the importance of a health examination.

Purposes:—1. You want all your hearers to go at once, to their own physicians and apply for a health examination; in other words, the purpose of your address is action.

2. There are two incentives toward action—1, emotion and, 2, intelligence. The stronger of these is emotion, (i.e., something that moves).

The most compelling incentive to action is negative—the pain and fear series. This appeal is easy to make effective; use it cautiously, never directly. While the main argument in favor of the health examinations is the avoidance of danger, the emphasis can be placed upon the *avoidance* rather than the danger. Use positive rather than negative motives, i.e., safety, avoidance of pain and disability. The examination costs less than an illness, and, as someone has said, an illness usually costs less than a funeral.

A health examination not only discovers illness so that it may be treated at best advantage before it is too late, but it also gives an opportunity to remove hidden handicaps which diminish *health, happiness* and *efficiency* and rob life of much of its pleasure. It also provides an opportunity to bring *benefits* which medical science can add to make even a healthy life richer and more vigorous. It can provide *safeguards* against troubles of the future.

A health examination, if properly conducted, will give a feeling of confidence and relief. The characteristic feeling is "now I know exactly where I stand, I know just what I have to do, and here is nothing unknown that I have to worry about." To the greatest degree possible, it takes the nagging uncertainties out of life. The feeling that one should have about the health examination is that it is a wise thing for a sensible person to do. It is painless, it is profitable.

Objections:—The following are some objections which the speaker may have to meet:

1. *Delay.* "Don't trouble trouble, until trouble troubles you," "let sleeping dogs lie," "if I have anything the matter with me, I don't want to know it." This is bravery rather than courage, the counsel of ignorance, a typical attitude of the fabled ostrich with his head in the sand.

This may be answered along this line:

When the enemy is launching an attack on the front line trenches, he seeks every cover to prevent notice by his intended victims. If the sentry cries out, "The enemy is coming!" do the soldiers turn over and reply, "Don't bother me, wait till they arrive, that is time enough! Why bother about the enemy until you have to, you destroy my peace of mind. You are borrowing trouble."

No, the soldiers arm themselves at once and seek to stop the attack before it gets under way.

Now, the enemies are the insidious chronic diseases and deteriorations (mention them if you like). Attack them before they can start their attack on you; for when thay get started, the attack is pressed close, and they are hard to fight. The sentry is the medical profession. He is now giving you his warning. You are the soldiers, seek out your medical captain, your own family doctor, and he will give you the correct orders to make your fight and remain happy and unharmed.

Other answers can be worked out. The value of foresight is demonstrated by wise and successful men in farming, business and profession. A little wisdom is worth much brave stupidity. "Wisdom is justified of her children." As Uncle Zeb says, "ignorance may be bliss, but it has raised many a blister."

2. *Pain.* "Why, I haven't had a pain, why should I worry, it does not hurt me?" Only the lower animals are stupid enough to wait for a pain before they take measures for their safety and many of the lower animals are very much wiser than that. Pain is the old biological signal for action. If you wait for a pain you will get it.

It cannot be too strongly emphasized that men have died of heart disease who have never had a pain in the heart. Men have died of diabetes and never had a pain. Men and women have died of cancer which had started and gone on without pain for one, two and three years, until the time for a saving operation was irrevocably passed and there was no remedy.

Men and women have had their hearts wrecked from rheumatism from teeth that never caused a pain because the roots had been killed. High blood pressure can go on for years without pain. Tuberculosis can go on for months without pain.

3. "I never had a sick day in my life. You doctors would starve if everybody were like me," accompanied by a thump on the chest and a haughty look. High blood pressure, nephritis and the like sometimes have pre-clinical symptoms unfortunately painless and euphoric. Try to be kindly with such a person.

Helps in Preparation:—The following articles will be helpful to the speaker:

1. "Manual of Suggestions for the conduct of Periodic Examinations of Healthy Persons." Send 20 cents to the American Medical Association, 535 North Dearborn Street, Chicago.

2. American Medical Association Blanks. Single copy 5c; 50 copies for 50c.

3. "What's a Health Examination Anyway?" Haven Emerson. American Medical Association 10c.

4. "Prophetic Medicine." Reprint from Scribner's Magazine, Popular article on Health Examinations, C. Ward Crampton, sent on request while available. 515 Park Avenue, New York.

5. Post-Graduate "Health Survey." Sixteen-page form for health examinations with aids for physicians and patients.

6. Health Book, to accompany the Health Sur-

vey, to be given to the patient after the examination, contains prescriptions and recommendations. Survey and Health Book may be obtained from the State Committee while available. 515 Park Avenue, New York.

7. "How to make a periodic health examination." Fisk and Crawford, Macmillan, New York. A good text book.

8. "Preventive Medicine." Published by the Academy of Medicine, New York City. Written by several authors. Published by Hoeber, New York.

Special requests should be addressed to C. Ward Crampton, M.D., 515 Park Avenue, State Chairman, of the Committee on Periodic Health Examinations or to the office of the Medical Society of the State of New York, 2 East 103rd Street, New York.

PART II. BRIEF NOTES ON THE SCIENTIFIC BACKGROUND

Definitions of the Health Examination:

a. The Medical examination of one presumably in health.

b. The inspection of a person (presumably in health) to find means to lengthen life, detect diseases or deterioration, to increase health, happiness and efficiency by every practical way open to a skilled and understanding medical advisor.

The *Health Examination Procedure* has three parts:—

1. *Diagnosis*—examination, consideration of findings, preparation of a practical program.

2. *Prescription*—instruction of client, motivation of program of cure, correction and betterment.

3. *Treatment*—The program of cure, correction and betterment is carried out by the health client under the guidance of the medical advisor, usually and by preference, the examiner.

Diagnosis:—The examination involves the determination not only of present disease, but also pre-clinical signs.

Present Disease:—To *discover present disease* not yet obvious to the client.

Caution—No one can exclude the presence of disease except by the most exhaustive search and then not positively, as for example myocarditis, early intestinal cancer.

Note:—The above, the search for present defect or disease, is all that a simple ordinary health examination contains. It is a good deal. It may be done by any physician who will faithfully search over the whole body.

Preclinical Signs:—To discover diseases in their preclinical stages or to discover conditions preclinical to disease or deterioration, i.e., *preclinical signs.*

Note:—We seldom see chronic diseases except in the XYZ or advanced stages. There is a preclinical chain of linked causes leading from far back in the *preclinical alphabet.*

Definitions of Preclinical

a. Evidence of disease discoverable before the clinical stage (Cline-bed; hence, disability).

b. Presymptomatic, i.e., before pain or disability noticeable to the patient.

c. Predispositions; prodomata.

Classification of Preclinical Signs

Conditional (by history).

1. Heredity (arteritis, hemophilia, etc., etc.).
2. Previous illness (immunological record, tonsillitis, scarlet fever, rheumatism, etc.).
3. Regimen (life management and environment; past and present: alcohol, malaria, tuberculosis).

Objective (by examination).

4. Anatomical, structural (body type, posture).
5. Physiological, tests and observation (circulation tests, carmine test).
6. Pathological:
   a. A disease in its preclinical stage (early diabetes, tuberculosis).
   b. Or a disease preclinical to another.

Note:—Preclinical signs of all classes differ in reliability, clarity and certainty, some are positive, others negative, some inclusive, others exclusive.

* * * *

Betterment:—To discover ways (not primarily related to disease) to add to the wealth of living (point of view, environment, exercise, diet, recreation, attitude, adjustment, life management).

"The human machine is coming in for its share of study and experimentation to increase its efficiency. The physician is the efficiency expert who must direct this service."—Page 7, Manual, American Medical Association.

* * * *

The Health Examination has two distinctive features:

1. It is the examination of a whole life, not the present illness alone. It studies the present in the light of the past and seeks to make the future full and secure. It is life time diagnosis and life time management.

2. It is extensive, rather than intensive. It faithfully covers the whole field of the body and all that affects it. The usual examination is focussed upon the particular illness.

Note:—There is a tendency to make medical examinations in the presence of illness more and more like the health examination, in these respects.

Reasons for the Health Examination:—Some dangerous diseases have a silent beginning period. Some of these diseases, if discovered early enough, may be stopped, such as tuberculosis, cancer, syphilis. (Caution—early discovery does not insure cure—for cure may be impossible.)

Some dangerous diseases, if discovered early, may be treated with profit though not as yet definitely curable. Diabetes, nephritis, cardiac disease, pernicious anæmia, and mental disease.

Conditions found within the body, in environment or in habits of life management may hinder and harass, and sooner or later invite disease and be dangerous to life—apical abscess, unsuitable work, dietary errors.

Impairment in happiness and efficiency consequent upon the above. Caution: No one should promise to lengthen the life of a single individual.

The body has an immense capacity of going on in spite of handicaps. It will endure much and keep on going. The health examination seeks to discover and remove these handicaps.

The mind can be trained to disregard pains, discomforts and go on. Some persons feel it creditable to endure.

* * * *

Evidence of the Value of Health Examinations:

Individual:—All of the reasons for the health examination have been realized in individual cases. Life shortening, life burdening and dangerous conditions have been removed.

General:—Statistical evidence shows that fewer persons died among a group of over six thousand given health examinations in the six-year period following the examination as compared with a similar group who were not examined.

No physician who has done health examinations has any question as to its value.

The health examination relieves subconscious worries about health. Persons who have health examinations say they feel better. Their families and friends agree.

* * * *

Common Understanding of the Health Examination:

I understand that something may be the matter with me that ought to be stopped before it gets bad. "A stitch in time, saves nine."

I have my automobile inspected, why not my body.

Varieties of the Health Examination:

The Insurance Examination:—For small policies, this is customarily a rough screening process to eliminate obviously bad risks. For large policies it is a moving toward the health examination ideal.

The Industrial Examination for Employment:—The prime motive is the protection of the employer from loss from or through illness or defect. It is valuable to the worker, when it reveals defects, especially if it moves toward correction.

The School Examination:—Primarily a rough screening process to exclude contagion, and find defects and latent infections. The State cannot properly go as far as the private physician may in the expenditure of time and attention.

Each condition noted below is a preclinical text which with examples from the speaker's own experience, may be presented with great profit.

Impairment	*Ages 25 to 34*	*Ages 45 to 54*
Faulty posture	16.9	20.8
Flat feet	17.0	15.4
Over 20% overweight	8.1	18.9
Defective vision uncorrected	28.9	29.4
Enlarged, septic or buried tonsils	32.8	17.1
Hypertrophic rhinitis, enlarged turbinates	16.9	10.7
Carious teeth; septic roots.	7.9	9.2
Heavy dentistry, roentgen ray advised	40.7	43.5
Slight arterial thickening	10.9	18.2
Blood pressure, up 20 or more	4.8	10.1
Constipation	39.5	40.1
Weak inguinal rings	5.9	5.9
Prostate gland, enlarged, hard, tender, boggy	2.0	5.6
Headache	16.4	13.7
Frequent colds	20.8	14.2
Urinary findings	25.9	32.4

Common defects; based on a study of 16,662 white males in the Metropolitan Life Insurance Company. From Dublin, Fisk, and Kopf, in the *American Journal of Medical Sciences*, October, 1925, No. 4.

THE USE AND ABUSE OF PHOTOTHERAPY*

By FRANK THOMAS WOODBURY B A M D NEW YORK N Y, LT COL U S ARMY, Retired

IN phototherapy, as in x ray and gamma ray therapy, the remedy is not the lamp used nor the radiation which it emits nor even the radiation which bathes the patient This misconception has led to much confusion in nomenclature with the consequent total loss of much labor and experience thus rendered meaningless

The real remedy in phototherapy is the energy produced within the cells when they absorb radiant energy

The radiant energy employed in phototherapy lies in the electromagnetic spectrum somewhere between wavelength (symbol λ) 180 millimicrons (symbol mμ) and λ14 microns (symbol μ) which are the limits at which this portion of the electromagnetic spectrum is absorbed by living cells Any wavelengths longer or shorter than this region in this part of the spectrum are reflected and of no value

When radiant energy is absorbed by living cells it is converted into heat, or chemical energy or both There are no other alternatives The various bio reactions to this converted energy constitute the basis of phototherapy

We give photochemical or photothermal or photochemicothermal treatments in phototherapeutic practice All phototherapeutic treatments fall of necessity into one of these three classes

*Photochemical Therapy or Photochemy***— Under the name of ultraviolet, photochemical effects obtained by radiant energy from metallic arc lamps especially the mercury arc in quartz have been so commercialized and misused in medical literature as to have not only obscured the entire subject of phototherapy but almost to have driven the rest of the phototherapeutic spectrum from the scene

Under the guise of sun lamps the general public, and many of the medical profession, have been lead to believe that the mercury vapor electric arc in quartz irradiates a spectrum possessing the same characteristics and imparting the same therapeutic results as in summer solar rays whereas its spectrum is interrupted and curtailed and contains wavelengths which are most chemically irritating to living cells, not found in solar radiation, and does not contain wavelengths of energy in the caloric region

This misconception that ultraviolet was an invariably fixed quality of chemical radiation interchangeable therapeutically with solar radiation led to indiscriminate use of any and every type of radiating apparatus and calling the method ultraviolet treatment Many unhappy clinical results and much disappointment resulted

Phototherapy can do without the mercury vapor arc in quartz because there are other sources of chemical rays more potent and not so restricted in effect

Living cells are selective in choosing which wavelengths of energy they will absorb The resulting energy thus converted in the cell itself is of markedly individual chemical nature peculiar to the substance acted upon Thus we have activation of ergosterol into viosterol or vitamin D by wavelengths between λ289 mμ and λ313 mμ. dermatitis by the region between λ250 mμ and 313 mμ, provided the person is white skinned, and pigment is caused by the region between λ300 mμ and λ320 mμ in persons who can form pigment It would seem that carotin, ingested as food, is activated into vitamin A by the yellow-green region while photoallergy from the visible spectrum sensitizing ingested food substances and dyes is not only an observed phenomenon but a method of photochemical treatment Blue rays are decidedly sedative and analgesic The blood absorbs all radiation reaching it less than λ450 mμ with two absorption bands at λ540 mμ and λ580 mμ and when sensitized, two others with maxima at λ600 mμ and λ660 mμ Absorption spectra give the key to therapeutics by radiant energy

Photoallergy has many resemblances as well as many contrasts when compared with the reactions obtained by radiation in the region λ289 mμ to λ313 mμ (called the Dorno region) and when applied to unpigmented individuals These I have treated more fully elsewhere [1]

Now the Dorno region is practically the essence of all the so called ultraviolet treatments since its energy when absorbed has very important effects upon the parathyroid glands and through them upon calcium and phosphorous utilization with all the functions depending upon that phenomenon It is therefore to be given whenever we have a condition marked by disturbed calcium and phosphorous utilization The conditions depending upon this disturbance present a wide range of indications for the chemical effects of the Dorno rays

It does not follow that the Dorno rays are the only wavelengths of chemical effects and therapeutic value Phelps of Yale" has, by means of a Corning glass filter (G986 A) and a continuous spectrum reduced the radiation in the ultraviolet region so that there was a maximum in the range from λ320 mμ to λ380 mμ and a minimum in the Dorno region Using this altered radiation he obtained what he believes is a demonstration of the specificity of the λ320 λ380 mμ energy in the treatment of tuberculosis

As a corroborative proof we have the work of Kramer *et al* [2] who demonstrate that in the study

* Read at the Annual Meeting of the Medical Society of the State of New York at Rochester, N Y, June 4th 1930

** This simplified term is suggested by the writer as possessing a clear and definite application

of eighteen tuberculous children, divided into two groups, vitamin D did not accelerate healing nor produce any increase in either serum calcium or phosphorous and no deleterious effects, ascribable to overdosage were witnessed.

The accumulated observations of many students of this subject have resulted in a mass of facts, inferences and deductions which have caused the subject to become considerably involved. If we carefully put to one side all the evidence obtained from plants and all the evidence obtained with protozoa and invertebrates and also the evidence from the experiments with animals which however have markedly different physiological processes from our own we may consider them as showing without possibility of cavil that all the frequencies of the solar spectrum which reach the surface of the earth either directly or by reflection or by dispersion have valuable vital effects upon living things.

We have also evidence that alteration of radiation by reduction, by elimination of parts of the spectrum or by overintensifying some wavelengths produces radiation so distorted as to have marked effects upon living things subjected to its continuous application.

With living human beings the processes intimately associated with vitamin influences such as growth, metabolism, the reproductive functions, the development of sexual characteristics, muscular strength, mental activity, nervous power are also profoundly influenced by the chemical effects of radiant energy.

The terms vital, extra vital and intravital have therefore no meaning since they do not by any means correspond with any reactions save those limited to the Dorno region.

We feel, therefore, that the term ultraviolet is meaningless as well as the term light to describe photochemical treatments.

Another term which has come into use but which is without meaning is the term "erythema dose." The term erythema, meaning merely a redness, has been abandoned, by the roentgenologists who first used it, as being meaningless. The phototherapists should do likewise. The reaction called erythema is a dermatitis, an inflammation of the skin, a sunburn in common parlance. One can also have a sunburn of the mucous membrane.

For what diseases is sunburn a form of treatment? Manifestly (1) where a revulsive reaction on deeper organs through the nervous system is indicated. (In such an event a mustard plaster or a mustard bath will serve every purpose.) (2) Where an inflammation is desired in order to produce a reactivation of old chronic keratoses and replace them by more normal cells and (3) where a very superficial germicidal action is desired. These are the limitations of sunburn as a remedy. You are again limited clinically, if your patient is already deeply pigmented racially or as the result of solar exposure, because he cannot sunburn.

The so-called ultraviolet rays are therefore, so far as their dermatitis reaction is concerned, restricted to dermatological practice[4] and even there the *x* rays have priority, and after them the entire spectrum and not that given off by mercury arcs in quartz.

A sunburn is indeed a calamity in the treatment of the constitutional diseases. Rollier, Sonne, Hill, Mayer and many other clinicians stress the necessity of giving photochemical treatments without sunburn. If the patient be already pigmented no caution is necessary but if he be unpigmented, a red blonde, an albino, an infant or if he have large areas of vitiligo on a pigmented ground then subinflammatory exposures must be given throughout the course of treatment.

It may be stated that the object of phototherapy is, with but very few dermatopathological exceptions, to administer the maximum photochemical energy without dermatitis and in conjunction with caloric rays by a spectrum resembling as nearly as possible that of the zenith summer sun.

This erythema dose idea totally disregards the erythema from caloric rays which is very important but very different as I[5] have pointed out elsewhere. The idea however that a sunburn is a treatment and that degrees of sunburn are doses rests upon the most fanciful of mental processes not susceptible of sound demonstration.

The pigmentation of those unpigmented is a protective measure of skins naturally sensitized to photochemical rays. This does not however interfere with the other photochemical effects of constitutional importance. Rickets for example is just as well treated in the colored as in the white child by Dorno rays. Coloring or dyeing the skin is not an equivalent substitute since the chemical rays will then be converted into heat unless the dye be a fluorescent one in which case the Dorno rays will not be emitted by it. There is a great difference between pigment in the epidermis and pigment in the stratum germinativum.

*Photothermal Therapy or Photothermy**—The second effect of absorption of radiant energy in this region is heat. It is a form of conversive heat resembling in many of its effects conversive heat from high frequency electric currents called diathermy.

These heat effects are found to be at a maximum, both of intensity and of penetration, at about $\lambda 770$ mμ. Both penetration and heat effect decrease rapidly as the wavelengths decrease so that for therapeutic purposes the heat effect is nil in the region of $\lambda 500$ mμ. though it may still be detected as far as $\lambda 180$ mμ. Penetration and heat effect decrease very rapidly as the wavelengths increase, becoming zero at about $\lambda 1.4$ mμ. It is to be noted that visibility and invisibility

* A term suggested by the writer as being simple and descriptive.

have nothing to do with phototherapy. They are terms belonging to the ophthalmologist and the painter and the illuminating engineer. Neither are we interested in the physicist's division into ultraviolet, visible and infra-red. Why? Because we are dealing with a remedy which is created in the cells themselves which is a result of wavelength and selective absorption and nature of the absorbing substances.

The effective absorption of the caloric rays and their conversion into heat coupled with their great penetrative power make photothermy a very close rival of diathermy. In fact there is very little that diathermy does which cannot be done also by photothermy. Although it may be spoken of as radiant heat we must remember that the radiation is not heat until it is absorbed by the cells. If there be little or no pigmentation, radiant energy in this region passes readily into the facial sinuses, the mastoid, the chest and abdominal cavity, through the scrotum, throat, tongue and maxillæ and the hands and feet. Pigment, pus, blood and solid growths absorb it as well as the muscles, fat, fascia and dense bone.

The reaction to photothermy is an active hyperemia. As such it is the extinguisher of the inflammatory reactions caused by photochemy and is therefore both a preventative and an antidote. It also brings about marked systemic reactions, depending upon the increased temperature, and it has distinct indications and contraindications which make it a remedy to be used only under the direction of a physician.

The sources of radiant energy producing both photothermal and photochemical effects is in heated bodies. Increasing the temperature of a substance causes it to emit electrons and consequently radiant energy. At a low degree of heat the energy emitted is in the longest infra-red region. As the temperature rises more and more wavelengths of energy are emitted progressively smaller in size until at a temperature of about 500° C. the frequency and wavelengths are small enough to cause visual perception of what is sensed as red light. As the temperature increases, more and shorter wavelengths are emitted until at a temperature of about 1400° C. the invisible ultraviolet wavelengths are added.

For every temperature degree there is one wavelength or frequency which is emitted in excess of all others. Therefore we may say that as temperature rises total radiant energy increases, the spectrum emitted extends toward the smaller wavelengths and the longer wavelengths increase proportionately.

The higher the temperature of our generator the greater will be the total quantity of energy absorbable as heat and also the more nearly will the spectrum resemble, in extent, that of the sun.

With generators of similar design the one operating at the highest wattage (volts x amperes passing through the lamp) will be the one whose spectrum will more nearly resemble the solar spectrum, because it operates at a higher temperature.

The common error of identifying heat with infra-red radiation is based upon the deliberate intention of commercial firms who have played up infra-red generators as though they were possessed of specific heat virtues for photothermy, and the uncritical repetition of the term by phototherapeutic writers. Some have attempted to avoid this error by speaking of "radiant light and heat." As light is nothing if not radiant we have an awkward tautology.

A piece of metal or carbon at a white incandescence will emit more energy utilizable as heat both relatively and proportionately than when it is at a dull red heat or is giving off only obscure rays, i.e., infra-red rays, as a black-hot body. Obscure heat rays form from sixty to ninety per cent of radiant energy from any incandescent source.

Infra-red radiators are therefore less effective than incandescent radiators since they not only emit less energy utilizable as heat but also because they operate at a lower temperature than incandescent radiators and therefore produce a greater proportion of their energy in wave lengths greater than 1.4 μ. which are not absorbed by the skin and are therefore wasted.

The long infra-red rays which are stopped by the epidermis and mucous membrane produce also chemical effects judging by the high degree of nervous irritability they cause and by a pigmentation though these effects are not the same as with ultraviolet short waves.

For these reasons phototherapy can do without the so-called infra-red radiators of obscure heat radiation.

Photochemicothermal Therapy or Heliotherapy—Since the rays of the sun as they reach this earth unobstructed by any medium except pure air have a spectrum extending from about λ289 mμ. to about λ3 μ. they contain wavelengths which are absorbed as chemical and as thermal energy, a photochemicothermal application.

If we modify this by filtration through various media we can greatly alter the proportion of thermal to chemical moieties. The same occurs if we reflect the rays from suitable reflectors or from ice, snow, sand and water or from skyshine and clouds.

For this reason any portion of the earth's surface may be selected for heliotherapeutic treatments which will afford a daily exposure of the nude body to direct, reflected and diffused solar radiation in a dustless atmosphere.
